Foreword

I am delighted to welcome you to the 2009 edition of the *APO Productivity Databook*. While releasing this new edition is a pleasure, the world is currently experiencing a global financial crisis which severely affects the economies of the APO region. Urgent but careful analysis of potential economic growth is thus being sought. In that connection, detailed productivity analyses are one among many other informative analytical sources for both public and private decision-makers to reassess the development engine of the economy and strategize how to overcome the challenge of economic stagnation.

This edition achieved some notable improvements compared to the 2008 edition in terms of precision and the coverage of the data presented for cross-country comparisons. The latest PPP estimates, which were revised at the 2005 International Comparison Program and published by the World Bank in 2008, are used for analyzing various productivity indicators to reflect a more realistic picture of the actual economy. The time-series coverage presented in this edition is also extended back from 1970 to 2006, and this enables readers to appreciate the status of the economy retrospectively at the time of the first oil shock in the early 1970s; this allows a comparison of a period of financial turmoil decades ago with the current one.

This publication is a tangible achievement of the APO Productivity Databook project, initiated by the Research and Planning Department of the APO Secretariat in collaboration with Keio Economic Observatory, Keio University. The APO is planning to strengthen its think-tank roles through this research project, to improve and expand further the harmonized productivity data and analysis as a part of its efforts to serve member countries in accelerating productivity and economic growth. With richer and wider analyses of the role and sources of productivity growth, it is hoped that this publication will be a useful guide for national and private policy-makers, as well as for the respective national productivity organizations, in identifying their development priorities and formulating need-based projects.

Lastly, I wish to thank all the national experts for providing the original national data in line with the APO methodology. Profound gratitude is extended to the team of productivity specialists—*cum*—authors of this publication at the Keio Economic Observatory, Professor Koji Nomura, Ms. Eunice Y. M. Lau and Mr. Hideyuki Mizobuchi, who have made significant contributions to upgrading the quality of the data and the methodology. This solid international comparison of productivity would not have been possible without their careful and meticulous work.

I hope that readers will appreciate the information provided in this publication and find practical use for it.

Shigeo Takenaka
Secretary-General
Tokyo, March 2009

1. Introduction

The Asian Productivity Organization (APO) is a regional intergovernmental organization, established in May 1961 as part of a productivity initiative to drive greater economic development in the Asia and Pacific region. The current APO membership comprises Bangladesh, Cambodia, the Republic of China (hereafter the ROC), Fiji, Hong Kong, India, Indonesia, Islamic Republic of Iran (hereafter Iran), Japan, the Republic of Korea (hereafter Korea), Lao People's Democratic Republic (hereafter Lao PDR), Malaysia, Mongolia, Nepal, Pakistan, the Philippines, Singapore, Sri Lanka, Thailand and Vietnam. It works through a network of national productivity organizations (NPOs) that are designated as official liaison bodies to implement APO projects and propel national productivity movement in their own countries. Serving as a think-tank and regional adviser for its 20 member economies, the APO, through its secretariat based in Tokyo, conducts research and surveys to identify common needs in the drive towards productivity so as to develop appropriate action plans that support its members' efforts in economic development via productivity enhancement. Another key function of the APO, among others, is to disseminate information and knowledge on productivity tools and methodologies across the region through seminars, conferences, workshops and study meetings.

1.1 APO Productivity Databook 2009

This is the second publication in the *APO Productivity Databook* series, which was relaunched last year. The results and analysis presented in this volume are based on the APO Productivity Database, constructed under the joint research effort of the APO and the Keio Economic Observatory at Keio University. The APO Productivity Database project was established in September 2007. In the past year research effort has been focused on building the basic structure of the database. Among other work areas, the APO productivity questionnaire was revamped to meet the data requirements of the APO Productivity Database better, with an expanded list of economic indicators and estimates. Metadata of countries' national

accounts were also collected in a survey appended to the APO questionnaire to build a knowledge base of cross-country data comparability. These improvements are reflected in this edition of the *APO Productivity Databook*.

In this report, results presented in last year's edition have been rerun with more harmonized data and definitions, made possible by the work input into the APO Productivity Database. In the questionnaire, national experts were requested to submit the whole time series. Consequently, the time series are not only updated with new data for 2006, but latest revisions to the back series are also included. Where there are discrepancies between the two editions, explanations are given.

New analysis and features have also been made available for this report. Baseline indicators (as presented in *Databook 2008*) are conducted for all 20 APO member economies (referred to as the APO20) and the three reference economies, namely the People's Republic of China (hereafter China), the US and the EU. However, due to data limitations, further analysis is not possible for all countries. Progressively more sophisticated measurements and analysis are therefore conducted for two further layers of country subgroups. For example, final demand analysis and real income comparisons are conducted for 17 APO member economies and the three reference economies, whereas total factor productivity estimates are constructed for three APO member economies (the ROC, Japan and Korea) and two reference economies (China and the US). While maintaining the inclusion of all APO member economies in our analysis of the basic indicators, analysis of labor productivity is deepened for countries where the data demand can be supported.

This project is directed and coordinated by Mukesh D. Bhattarai and Yasuko Asano of the APO Research and Planning Department, and managed by Koji Nomura of Keio Economic Observatory (KEO) at Keio University. The questionnaire was designed by a research team of the APO Productivity Database project and sent to the national experts (listed in Section 1.2) in time for the project coordination meeting held on 20–22 May 2008 in Bangladesh. The submitted data were examined and processed by the research team at KEO, led by Koji Nomura, who in conjunction with Eunice Lau and

Hideyuki Mizobuchi prepared the text, tables and figures presented in this report.

2. Overview

Between *Databook 2008* and this report, what a year it has been for the global economy! First oil prices rose relentlessly, peaking in mid-July at \$147 per barrel. Coupled with the rise in food and commodity prices, inflation was edging up worldwide. As food prices account for 30–40 per cent of the consumer price index in most emerging economies where per capita income is low, Asia faced a bigger inflation threat than richer economies. Indeed, in the first half of 2008 rapidly rising inflation posed one of the biggest threats to economic stability and future growth in Asia, with inflation reaching double-digit figures in Vietnam and Pakistan, and accelerating fast in many other countries.

Just as the inflation pressure was ebbing, with oil down to \$40 per barrel by year-end from its mid-July peak, and lower food and commodity prices, the world economy was gripped by another crisis. At the time of writing, an important chapter of economic history has been turned. The world economy is currently reeling under the weight of the worst financial crisis since the Great Depression of the 1930s. The credit crunch, which started in August 2007, has its origin in the collapse of the subprime mortgage market in the US. The financial contagion then spread through complex modern financial devices such as securitization, credit-default swaps and collateralized debt obligations, financed with enormous leverage and short-term debt. One year on, the crisis has intensified and broadened far and wide, crippling the world's finances and culminating in major bank failures at an unprecedented scale and rate.

The systematic bank failures, the drying up of credit and the burst of the property market bubble are feeding through to impact on the real economy, forcing businesses and households to retrench. There is no halting of the structural correction in the developed world, and it is anticipated to be particularly painful in the US and the UK. Governments and central banks of G-7 countries have responded to the situation with equally unprecedented rescue packages and coordinated interest rate cuts, pumping liquidity into the financial system and extending government bank guarantees. But it is

widely believed that these efforts are unlikely to avert a global recession.

Until the last quarter of 2008 cautious optimism had been held out for Asia and other emerging economies, based on the observation that economic activity in emerging economies had diverged from that of the developed world over the past two decades.¹ This decoupling theory is built on several factors. First, the emerging economies are less reliant on the US and have been trading more with each other, which now accounts for over half their total exports. Secondly, the rise in domestic spending has been strong in the emerging economies. In 2007 emerging economies' real domestic demand grew by 8 per cent on average, almost four times as fast as in the developed world. Thirdly, with strong macroeconomic fundamentals, today's Asia can better defend itself against economic shocks. Most countries hold large volumes of foreign exchange reserves and budgets which are in surplus or close to balance, both of which provide policy flexibility to respond if need be. Although not totally immune, it was argued that a downturn in the US should have a lesser impact on Asia than in the past. This was why growth was expected only to soften in the fast-growing emerging economies despite recession in the US and Europe.

Lately, however, the adverse impact of the global financial crisis is beginning to be felt in the emerging economies. It is worth noting that the conventional definition of an economic recession, i.e. two consecutive quarters of contracting output, does not apply to Asia, a region where populations are often younger than in the US and Europe, and the labor force is growing more quickly thanks to the process of urban migration. Consequently, most Asian countries, excluding Japan, require economic growth of 5 per cent or more to absorb those new workers from the rural areas. Based on this, it has been argued that a recession effectively occurs when the region-wide growth rate slows to 5–6 per cent. The corresponding figure for China is likely to be higher, at 8 per cent, after multiple years of double-digit growth. Many economists now expect GDP growth in China to slow to 7 per cent in 2009, down from 13 per cent in 2007 and its slowest for almost two decades. The

¹ See Akin (2007).

pain of a growth recession in Asian countries will be as acute as an outright recession with falling output in the developed economies. By this definition for the region, some Asian countries are already in recession while others are teetering on the edge.

Asia's export-led economies look more vulnerable than others following the collapse of global demand. Output is already falling in Singapore, Hong Kong and the ROC. Japan is also looking weak on the back of falling exports and slowing investment. As countries can no longer rely on foreign demand, domestic demand (whether from households or government) will probably need to pick up the slack in bolstering economic growth. In today's increasingly integrated capital markets, it is inevitable that Asian countries have been caught up in the current global financial storm. After the first-round direct effect, the markets are now reacting to the retrenchment in the real economy caused by the financial crisis. Wealth is being squeezed as asset prices decline, dampening domestic confidence. Foreign capital had also dried up. However, this is counterbalanced by the resolve of the Asian governments, especially China, which are prepared and in a position to stimulate growth. Structural reforms and better macroeconomic policy for the past decade may have positioned these economies to bounce back faster than the developed economies; but it is probably too early to write off the decoupling theory completely.

How resilient an economy is in the face of serious external shocks depends on its economic structure and characteristics. In focusing on the long-term analysis, this report looks into Asian countries' economic composition and sources of growth in order to identify their strengths and the challenges ahead. In addition to *Databook 2008*, this edition includes three new sections.

1. The demand-side analysis is constructed for nearly all countries to complement the supply-side story, looking into the final demand shares of GDP and decomposing GDP growth into household consumption, investment, government consumption and net exports.
2. Real income growth, as opposed to real GDP growth, is estimated for nearly all countries, explicitly measuring the impact of the terms-of-trade effect on an economy's purchasing power.
3. A volume index of capital services and total factor productivity growth are estimated and compared for the ROC, Japan and Korea, with China and the US serving as the reference countries. Within this framework, labor productivity growth can be decomposed into contributions from capital deepening and total factor productivity growth.

International comparisons of economic performance are never a precise science, but are fraught with measurement and data comparability issues. Despite our best effort in aligning the data, some data uncertainty remains. As we operate in a reality of incomplete information, some adjustments made are necessarily conjectural while others are based on assumptions. In addressing this shortcoming, conclusions drawn are cross-referenced against other similar studies. However, the magnitude of economic indicators and differences could be subject to a higher degree of data uncertainty.

Bearing in mind these caveats, the main findings from our analysis are as follows.

Economic scale and growth

- ◆ Our data show the outcome of the dramatic development effort made by the four Asian Tigers (namely Singapore, Hong Kong, the ROC and Korea), which, together with Japan, are seen consistently to top the Asian countries on level indicators, such as per capita GDP and labor productivity.
- ◆ After adjusting for the differences in purchasing power, the combined PPP-GDP of APO20 economies had reached a similar level to that of the US and the EU15 by 2006. If China is included, the total Asian economy overtook the US economy in size in 1990 and was 44 per cent larger than the US and 54 per cent larger than the EU15 in 2006.
- ◆ As the Chinese economy pulls ahead, its growing dominance in Asia can be seen by the fact that the sizes of other economies have been shrinking relative to it. In contrast, the relative sizes of economies against Japan have been increasing.
- ◆ Between 2000 and 2006 economic growth in the Asian economy based on PPP-GDP was 3.2 per cent faster than the US economy on average per year (2.4 per cent), 63 per cent of which was accounted for by China, followed by India, contributing 21 per cent to the region's relative expansion. Japan was the only country in Asia that grew more slowly than the US during this period, and was hence a drag on the region's relative growth against the US.
- ◆ China and India have been driving the regional economy over the past decade, with the former accounting for just under 50 per cent of the re-

gion's growth and the latter for 17 per cent. There were faster-growing economies in Asia, but their sizes were too small to make a significant impact on regional growth.

Catching up in per capita GDP

- ◆ In terms of per capita PPP-GDP, Singapore has not only caught up with the US, but has even overtaken it since 2005 and surpassed it by 9.6 per cent in 2006. This is followed by Hong Kong and Japan, with a per capita PPP-GDP equivalent to 90 per cent and 75 per cent of the US level respectively. In contrast, the APO20 as a group has not caught up much with the US, with a per capita GDP equivalent to around 13 per cent of the US level.
- ◆ This huge gap in per capita GDP is predominantly explained by Asian countries' relative labor productivity performance. Except for the four Asian Tigers, Japan and Iran, all the other Asian countries have a labor productivity gap of more than 60 per cent against the US. Most countries also have employment rates that fall short of the US level, substantially in some cases, further reinforcing their productivity performance. In 2006 Singapore was the only country which had effectively closed the labor productivity gap with the US, while six APO economies and China had higher employment rates than the US.
- ◆ Similarly, labor productivity growth also explained most of the per capita GDP growth in the past decade in most countries, except for Pakistan and Fiji, where employment played a bigger role. However, this should not lead us to underestimate the role played by the employment rate, as it accounted for over 25 per cent of per capita GDP growth in seven of the APO member economies between 2000 and 2006.
- ◆ The lower share of household consumption in the EU15 has been made up by a larger share of government consumption, which accounts for around 20 per cent of its nominal GDP. This compares with 14–15 per cent in Asia and 14–16 per cent in the US.
- ◆ Asia on average invests a lot more than the US or EU15 and has been sustaining an investment share in the region of the upper 20s to 30 per cent of GDP, compared to 20 per cent for the US and EU15. The share of investment in China is phenomenal, at 43 per cent in 2006, and has overtaken household consumption as the biggest final demand component of GDP since 2004.
- ◆ Net exports are gaining weight in the Asian economy, rising from 0.8 per cent of GDP in 1995 to 3.4 per cent in 2006. China explained most of the strengthening between 2000 and 2006. In contrast, the deficit between exports and imports in the US has quadrupled to 5.9 per cent of GDP in the past decade. A deficit in net exports tends to be associated with high household consumption, and countries with the highest household consumption share are also those with low income. These countries may struggle to defer consumption in order to invest.
- ◆ The main engine of growth for most countries during the period 1995–2000 was household consumption. The Asian financial crisis seemed to hit investment growth the most. For some countries, however, net exports were the real driving force, accounting for around 60 per cent of economic growth in Korea and Hong Kong, for example.
- ◆ On the back of the Asian financial crisis, the fastest-growing economies in Asia during 2000–2006 were propelled by investment growth (for example, in China, Vietnam and Cambodia). Net exports accounted for half to three-quarters of economic growth in Singapore, Hong Kong and the ROC. The contribution of net exports to economic growth in China also doubled between the two years. Overall, net exports have been a significant driver in Asia and subject to wider swings when compared to the US and EU15.
- ◆ From countries' annual data, the Asian financial crisis marked an exceptional time for many of the Asian economies, causing investment to nose-dive in 1998 and consumption to fall, albeit to a

The demand-side story

- ◆ Comparing the final demand shares of GDP shows that the Asian regional economy and the three reference economies are very different in their economic structures. Household consumption share is comparable between the APO and EU15 economies in the upper 50 per cent range. China and the US represent polar economies where household consumption share in 2006 was the lowest at 36 per cent and the highest at nearly 70 per cent respectively.

lesser extent. Net export growth, on the other hand, was exceptionally strong in some of these countries, likely to have benefited from the rapid devaluation of the Asian currencies at the time of crisis. Similarly, the impact of the dot.com crash is also visible from the data, most notably in the ROC.

Real income and terms of trade

- ◆ Real GDP systematically underestimates (overestimates) growth in real income when terms of trade improves (deteriorates). In the current global financial storm, volatile exchange rates are observed. To the extent that import and export prices are partially determined by exchange rate movements, the distinction between real GDP and real income may well become more significant for this turbulent period.
- ◆ This is backed up by our findings for the periods when Asian economies were faced by major economic shocks: the two oil price hikes of 1973–1974 and 1978–1979, and the Asian financial crisis of the late 1990s.
- ◆ Real income growth can be fully attributed to real GDP growth and trading gain. Trading gain is found to have a larger impact over shorter periods than over long periods of time. Even so, its contribution to real income growth can still be significant for some countries, with the average annual real GDP growth underestimating that of real income by 12 per cent and 18 per cent in Malaysia and Indonesia, for example, over the period 1970–2006. Over shorter periods of time, the difference between real GDP growth and real income growth could be as much as ± 40 per cent in some countries, which is caused by trading gain.

Whole-economy productivity performance

- ◆ We observe that the Asian countries that are catching up fast with the US in per capita GDP were also rapidly closing the labor productivity gap with the US, and had both the highest and a rising labor utilization rate over the past three decades. For countries where there was no catch-up or that saw a decline in relative per capita GDP, it was their productivity performance that distinguished them.
- ◆ In terms of labor productivity (measured as GDP per worker), Singapore effectively closed the gap

with the US in 2006. Hong Kong comes second with a gap of 12 per cent, while Japan and the ROC have a gap of around 30 per cent against the US. Productivity levels of the majority of the Asian countries, however, are less than 20 per cent that of the US, pulling down the average performance of the group to 15 per cent for the APO20. Included in this long tail were China and India, with productivity levels of 9.4 per cent and 6.4 per cent of the US level, respectively.

- ◆ Estimates of total factor productivity (TFP) growth for four countries are presented. Japan and Korea have similar TFP growth, which averages to 0.5–0.7 per cent a year over the period 1970–2006. At 1.6 per cent, TFP growth is stronger in the ROC. China is a league of its own, achieving an average annual TFP growth of 3.1 per cent over the same period. The estimate for China is comparable with those of similar studies.
- ◆ Economic growth can be decomposed into sources from factor inputs (labor and capital) and TFP. The sources of economic growth are considerably different among countries. The main engine in Japan was an expansion in capital input, contributing about 82 per cent of the economic growth during the period 1970–2006. TFP contribution was 17 per cent. The split of 75 per cent and 8 per cent for Korea is similar to that of Japan.
- ◆ Although, over a long period of time, capital accumulation has played a much more significant role in Asian countries than in the US, the relative contribution shares are not constant over time. There were periods when TFP growth increased its weight in driving growth, particularly in recent years. There was a resurgence in TFP growth during the period 2000–2006 in Japan and Korea after the Asian financial crisis, raising its contribution to economic growth to a significant level (80 per cent for Japan and 41 per cent in Korea). For the ROC and China, the golden period for TFP growth and contribution was between 1985 and 1995.
- ◆ In our estimation we find evidence of a capital allocation shift towards IT capital in Japan, Korea and the ROC, although the timing was slightly different. By doing this, Asian countries are poisoning themselves to benefit from the advancements in information and communication technology.

- ◆ Within the growth accounting framework, labor productivity growth can be attributed to capital deepening and TFP growth. Over the long term (i.e. 1970–2006), labor productivity growth is predominantly explained by capital deepening in Japan (83 per cent) and Korea (88 per cent). In the ROC, capital deepening explains 68 per cent and TFP 32 per cent of labor productivity growth. In China, however, the split is roughly half and half.
- ◆ Over shorter periods, it is possible to see that the role played by TFP has weakened in the ROC whereas it has strengthened in Japan, accounting for 16 per cent and 54 per cent of their labor productivity growth respectively.

Industry performance

- ◆ Looking at the industry structure of the Asian countries compared, we find a broad negative correlation between the size of the agricultural sector and the relative per capita GDP against the US. In other words, the more an economy relies on its agricultural sector, the poorer the country is.
- ◆ The service sector accounts for the largest share of the economy in all country groups, independent of their economic development.
- ◆ Each stage of economic development is associated with a distinctive industry structure. Countries with the highest per capita GDP have the largest service sector, whereas the lowest per capita GDP group has the largest agricultural sector. In between are economies in transition, with a rapidly shrinking agricultural sector and a relatively prominent manufacturing sector.
- ◆ Breaking down economic growth into industry origin, we observe the above-the-norm dominance of the manufacturing sector in some of the fastest-growing economies. For example, manufacturing in China accounted for 47–48 per cent of economic growth between 1995 and 2006. In Korea and Thailand, its contribution is also above 40 per cent. In contrast, the story behind India's recent growth has been about services,

accounting for 63 per cent of economic growth for the period 2000–2006, compared with 16 per cent from manufacturing. This affirms the divergence of growth patterns in China and India.

- ◆ Labor productivity accelerated in 2000–2006 to an average of 1.7 per cent per year for the APO20 and 3.9 per cent if China is included, from 0.7 per cent and 2.4 per cent respectively over the period 1995–2000. The contribution from agriculture was around 15 per cent during the latter period, while manufacturing and services made very similar contributions of 39 per cent and 37 per cent respectively to labor productivity growth.
- ◆ Preliminary evidence suggests that service sector labor productivity is largely driven by subsectors which are potentially IT-using in recent years (accounting for 60 per cent of service sector labor productivity growth in China and 86 per cent in India).
- ◆ In line with other countries' experiences, aggregate labor productivity in Asia has been predominantly driven by the intra-sectoral effect – that is, productivity improvement within the industry sector. Even so, the inter-sectoral effect, which reflects changes in the allocation of production, can contribute up to 21 per cent to labor productivity growth in Pakistan and 11 per cent in Bangladesh, or can drag labor productivity growth down by as much as 9 per cent in Iran.

Asia is a diverse regional economy within which countries have embarked on their own journeys of economic development at different times and different paces. When taking a snapshot of cross-country comparisons of various economic indicators for recent years, we find that nearly all countries are making concerted efforts to move away from agriculture, as reflected in the long-term declining trend in total value added and total employment in the region. In the process, labor productivity has improved. The immediate challenges that lie ahead for the fast-growing economies in Asia are how best to manage their economies and sail through the current global financial and economic storm without significantly setting back their development efforts.

3. Economic Growth of the Asian Countries and Region

Underlying international-level comparisons of GDP and other related performance indicators is a set of conversion rates between the individual national currencies and a common currency unit (customarily the US dollar). In this context, purchasing power parities (PPPs) are the preferred currency converters. By taking into account the international price differentials, PPPs rectify the traded sector bias, which is embodied in market exchange rates, and in turn the relative size of economies can be more adequately measured (see Box 1 for details). It is therefore important to note that any international GDP comparisons are sensitive to both GDP revisions and revisions to multilateral PPPs. These revisions explain the differences in results between the two editions of the *APO Databook*.

In this edition, the GDP revisions originated by the national statistical offices are negligible.² In contrast, PPP revisions are substantial in this edition following the 2005 benchmarking round of the International Comparisons Program (ICP). A bilateral PPP is a conversion rate that equalizes a country's price level for a comparable basket of expenditure with that in the US (customarily the benchmark country). PPPs therefore convert national GDP and other related indicators into standardized volume terms for comparisons, important for illuminating issues of global interest such as the relative sizes of economies, poverty rates, productivity and expenditure on education, health and investment.

Compared with the previous estimates, PPP revisions in this benchmarking round are large (see Box 1). For most of the countries covered by the *Databook*, PPPs have been revised upward, substantially in some countries, e.g. by 65 per cent for China and 55

per cent for India. The revisions have the impact of reducing PPP-based GDP (hereafter PPP-GDP), e.g. by 40 per cent for China and 35 per cent for India. Among the handful of countries which have downward revisions to their PPPs, Singapore has the biggest revision of 71.5 per cent, which in turn increases its PPP-GDP by 40 per cent. The combined results have considerably altered our view of the relative sizes of economies, even though national real outputs are unchanged. This forms the backdrop for our results in this edition of the *Databook*.

3.1 Economic Scale and Growth

Table 1 ranks Asian countries by their GDP at current market prices, using market exchange rates³ as the currency converters, in the years 1980, 2000, 2005 and 2006. There are few revisions to the data when compared with *Databook 2008*, and they are largely results of small national GDP revisions. Japan topped the table, followed by China, in all four years of comparison. In 2006 Japan's economy was about one-third the size of that of the US and 36 per cent that of the EU15.⁴ China's GDP was 62.8 per cent⁵ that of Japan or 22.6 per cent of the US. India followed, with a size very similar to that of Korea, equivalent to around 20.4 per cent of Japan's GDP. Except the smallest economies, all economies have grown in size relative to Japan, eroding its lead. APO member economies, excluding Japan, as a group achieved 86.6 per cent of Japan's GDP in 2006, up from 73.4 per cent in 2005. When China is included, the size of Asia21⁶ minus Japan was 149.4 per cent of Japan's GDP in 2006, compared with 123.5 per cent in 2005. By this measure, the size of

2 However, the APO Productivity Database includes adjustments made to harmonize GDP coverage better across countries. The decision to exclude FISIM (financial intermediation services indirectly measured) and include software investment is detailed in Box 2. The methods employed and the magnitudes of adjustments made are provided in Box 3.

3 The data source for market exchange rates (period average) is the World Bank's World Development Indicators.

4 The EU15 countries are Austria, Belgium, Denmark, Finland, France, Germany, Greece, Ireland, Italy, Luxembourg, Netherlands, Portugal, Spain, Sweden and the UK.

5 The growth of China has been a subject of controversy. Madison (1998) has argued that China's growth rate was overes-

timated by 2.4 per cent per annum during the period 1952–1995. However, official estimates have recently been revised upward to correct for an underestimation of the service sector for the period 1993–2004, while others continue to argue that the growth of China is overstated as a result of an underestimation of price inflation. In this report, Chinese data are taken from different data sources, such as *China Statistical Yearbook and Data of Gross Domestic Product of China 1952–2004*. Further detailed information on data sources is found in Section 9.2. Holz (2006) provides a useful reference on Chinese official statistics.

6 Asia21 consists of the APO20 plus China.

Table 1: Cross-country Comparisons of GDP in 1980, 2000, 2005 and 2006

1980			2000			2005			2006		
Japan	1,061,324	100.0%	Japan	4,705,981	100.0%	Japan	4,595,439	100.0%	Japan	4,415,392	100.0%

Unit: Millions of US dollars at current market prices

Asia's GDP was only 89.7 per cent that of the US in 2006. The corresponding figures for the APO20 and ASEAN8⁷ were 67.1 per cent and 8.6 per cent respectively.

The rankings, however, change dramatically when international price differences are properly accounted for. Developing countries tend to have relatively lower wages and in turn lower domestic prices for non-traded goods and services. Hence a unit of local currency has greater purchasing power in the local economy than reflected in its market exchange rate, which is influenced mainly by traded goods

and services. Consequently, using market exchange rates for cross-country GDP comparisons tends to underestimate the relative size of developing economies.

Table 2 corrects this bias and presents the rankings of PPP-GDP⁸ at current market prices for Asian countries in 1980, 2000, 2005 and 2006. Based on PPP-GDP, the relative size of China's economy in 2006 more than doubled to 155.4 per cent that of Japan, compared with 62.8 per cent when the market exchange rate is used. Similarly, its size increased from 22.6 per cent to 49.5 per cent relative to the US

7 The ASEAN8 countries are Cambodia, Indonesia, Lao PDR, Malaysia, the Philippines, Singapore, Thailand and Vietnam; Brunei and Myanmar are not included.

8 Caution should be exercised when comparing economies by their GDP and other related indicators. Mindful that there may be errors in the calculation of GDP and other variables,

as well as in the estimation of PPPs, small differences should not be considered as significant. It is generally accepted that differences in GDP of less than 5 per cent lie within the margin of error of PPP estimation. Rather than ranking economies, it is preferable to group economies by broad size categories (see World Bank, 2008).

Table 2: Cross-country Comparisons of PPP-GDP in 1980, 2000, 2005 and 2006

1980			2000			2005			2006

Unit: Millions of US dollars at current market prices

economy. On this measure, China's economy has overtaken Japan since 2001 to become the biggest in Asia. This represents remarkable growth considering that the Chinese economy was only 23.9 per cent that of Japan in 1980. The relative size of the Indian economy is also more accurately reflected as 65.8 per cent, instead of 20.4 per cent, when compared with Japan in 2006, and equivalent to 2.5 times the size of the Korean economy.

Table 2 shows the growing dominance of the Chinese economy as it pulls ahead and reduces the sizes of other economies relative to its own. For example, between 2000 and 2006 Japan shrank from 110 per cent to 64 per cent, the US from 329 per cent to 206 per cent and the EU15 from 319 per

cent to 192 per cent relative to China. Even India, a fast-growing economy, could not match China, with its relative size reduced from 51 per cent to 42 per cent that of China. In contrast, the relative sizes of economies against Japan have been increasing, as reflected in these snapshot comparisons.

The combined size of the Asia21 is now 44 per cent larger than the US economy and 54 per cent larger than the EU15. Even excluding China, the APO20 as a group is similar in size to the US economy and EU15, equivalent to 95 per cent of the former and 102 per cent of the latter in 2006. On this basis, Asia is a regional economy to be reckoned with.

Box 1: Purchasing Power Parities: 2005 Benchmark and Its Impact on GDP Comparisons

It has long been recognized that using exchange rates to compare the levels of economic activity between economies can give rise to misleading results. On the one hand, market exchange rates are subject to short-term, and at times substantial, fluctuations from speculative capital movements and government intervention. Consequently, cross-country comparisons based on market exchange rates could appear arbitrary, depending on which period of market exchanges is used. On the other hand, market exchange rates could be fixed or managed by policy in some countries. The relative sizes of these countries will therefore be partially determined by a policy parameter, not the underlying economic fundamentals.

As the prices at which currencies trade in the international market, market exchange rates also suffer from "traded-sector bias", i.e. they are influenced by the prices of traded goods across countries, but not by the domestic prices of non-traded goods. As developing economies tend to have relatively lower wages and in turn lower prices for non-traded goods and services, a unit of local currency has greater purchasing power within a developing economy than it does in the global market. Therefore, comparisons based on market exchange rates typically underestimate the size of a developing economy and the perceived welfare of its residents. However, this does not mean that PPPs should be used for all international comparisons. In measuring international trade, capital flows and the values of foreign debts, for example, it is appropriate to use market exchange rates.

Multilateral PPPs are statistical estimates expressed in a base currency, customarily the US dollar. They show the equivalent cost of a comparable basket of goods and services, worth \$1 in the US, in the national currencies of the respective countries. The data source for global PPP estimates is the International Comparisons Program (ICP), a worldwide statistical initiative led and coordinated by the World Bank with five ICP regional offices and in close partnership with Eurostat-OECD. From the initial round of 10 countries in 1970, the coverage has been expanded to 146

countries in the latest round, spanning from 2003 to 2008, to produce the 2005 benchmarks, accounting for 95 per cent of the world's population and 98 per cent of the world's nominal GDP. The latest benchmark results are extrapolated backward and forward using relative GDP deflators to create a time series, superseding the previous series based on the 1993 benchmarks, which were used in *Databook 2008*.

PPP revisions can be traced back to various sources: changes in economic structures, which are not reflected in extrapolation, are updated with each benchmarking round; the product list is different in successive rounds; methodological improvements also lead to inconsistent results when compared with the previous round; and PPPs are results derived from a multilateral estimating process, and the bilateral relationships are affected by indirect parities with all other economies in the region. For China, which joined the ICP for the first time, and India, which participated for the first time since 1985, it is not surprising that the combined impact of these factors on their previous PPP estimates is substantial.

Figure B1 shows the revisions to the previous PPP estimates for 2005 as a result of the 2005 benchmarking exercise. For the 20 Asian countries covered by the *Databook 2008*, 16 have their 2005 PPPs revised upward. Revisions for some countries are substantial, e.g. 93.5 per cent for Cambodia, 65.4 per cent for China and 55.4 per cent for India. Four countries have their PPPs revised downward: Singapore, Iran and marginally for Malaysia and Mongolia. The impact of an upward PPP revision is to reduce PPP-GDP, and vice versa. The PPP-GDP in 2005 is reduced by 39.5 per cent for China and 35.6 per cent for India, while it is increased by 39.9 per cent for Singapore. These substantial revisions have considerably altered our view of the Asian economy relative to the world leaders, as presented in this report. See Asian Development Bank (2007) and World Bank (2008) for more background information on PPP revisions and the ICP 2005 benchmark.

Figure B1: Revisions to PPP Estimates for 2005

Box 2: Metadata Survey on National Accounts in Asia

Understanding data comparability is essential for the construction of an international database, and requires significant effort and expert knowledge. Between April and July 2008 a survey on the national accounts and other statistical data required for international comparisons of productivity was conducted among the APO member countries for this project. The aim of this survey was to gather the metadata of the input data series required to populate the APO Productivity Database. Through the survey response, the project team has benefited from the knowledge of national experts of the participating countries. The metadata survey will be updated annually under the APO Productivity Database project. For detailed survey responses, see Nomura, Lau and Mizobuchi (2008).

Broadly speaking, cross-country data inconsistency can arise from variations in one or more of the three aspects of a statistic: definitions, coverage and methodology. The international definitions and guidelines work to standardize countries' measurement effort, but country data can deviate from the international best practice and vary in terms of omissions and coverage achieved. Last but not least, countries can also vary in their estimation methodology and assumptions, which may account for part of the differences we observe in the data and interfere with comparisons of countries' underlying economic performance.

Most of the economic performance indicators in this report are GDP-related. The survey therefore put a lot of emphasis on finding out countries' GDP compilation practices. For GDP, we take the System of National Accounts 1993 (1993 SNA) as the standard, and note how countries' practices deviate from it. Since there are differences between the 1993 SNA and its predecessor (1968 SNA) in some concepts and coverage, it matters to know in which year in the data series definitions and classification started to switch over, so as to identify breaks in the time series. Countries can differ in their year of implementation, the extent of compliance and backward estimates available.

According to our survey response, most APO countries are currently 1993 SNA-compliant, although for some countries the switch-over was only a recent affair. The starting year of the official 1993 SNA-compliant time series therefore varies a great deal across countries, reflecting the difference in the availability of backward estimates. The earliest year of consistent time series available for all 1993 SNA-compliant

countries in the APO Productivity Database is 2000. Countries may have adopted the 1993 SNA as the framework for their national accounts, but the extent of compliance in terms of coverage may still vary. Our survey findings highlight two areas which require alignments to improve comparability: the treatment of FISIM (financial intermediation services indirectly measured) and the capitalization of software.

FISIM is an indirect measure of the value of financial intermediation services provided, but for which financial institutions do not charge explicitly (para. 6.124). It represents a significant part of the income of the financial sector. The 1993 SNA recommends that FISIM should be allocated to users (to individual industries and final demands). This is in contrast to the 1968 SNA, where the imputed banking services were allocated exclusively to the business sector. The common practice was to create a notional industry which buys the entire service as an intermediate expense and generates an equivalent negative value added. As such, the imputed banking services have no impact on GDP. Therefore the 1993 SNA recommendation, if fully implemented, will impact on industry GDP and the overall GDP for the total economy (by the part of FISIM allocated to final demands). Among the 20 APO member economies, seven countries have incorporated FISIM in their GDP. However, only three countries out of these allocate FISIM to final demands. Due to the lack of information to adjust the data properly, our current decision is to harmonize the data by *excluding* FISIM from GDP for all countries in the APO Productivity Database.

The 1993 SNA also recommends the capitalization of intangible assets, which changes not only the size of GDP but also the size of capital input. One intangible asset is computer software, which includes pre-packaged software, custom software and own-account software. Due to its relevance to today's economy, there has been a major international effort recently to standardize its inclusion and estimation methods (see Nadim, 2003; Lequiller et al., 2003). Among the APO member countries, only three have capitalized all three types of software. Another six countries exclude own-account software in their software capitalization, and in one country only custom software is capitalized. For the APO Productivity Database, an adjustment has been tentatively conducted to harmonize data to *include* software. Please see Box 3 for details of the adjustment.

Box 3: GDP Coverage Adjustments for FISIM and Software Investment: Methods and Magnitude

FISIM

Among the 20 APO member countries, only the ROC, India and Korea allocate FISIM to final demands in their national accounts, as does the US as a reference country in this report. Our current decision is to harmonize the data by *excluding* FISIM from GDP for all countries in the APO Productivity Database. For the ROC and Korea (see Cho, 2000; Ahn, 2008), although FISIM or the imputed banking service charge is available, information on the proportion which has been allocated to the final demands is not available. We tentatively impute this proportion using the average of the ratios of Japanese trial estimates (by the Economic Social Research Institute, Cabinet Office of Japan) calculated over the period 1995–2006. This average comes up as 45 per cent. The proportions by which our adjustments for FISIM reduce GDP of these four countries in 2006 are 3.7 per cent of GDP (ROC), 1.9 per cent (India), 2.2 per cent (Korea) and 1.7 per cent (the US).

Software

The treatment of software also varies across countries. Among the countries studied, software investment is available only for the ROC, Japan, Korea and China. To harmonize data, a country's GDP is adjusted to include software investment (through its software industry) by using the ratio between software investment and GDP (hereafter software ratio) and the tangible GFCF to GDP ratio (hereafter GFCF ratio). Data from the OECD Productivity Database (Schreyer, Bignon and Dupont, 2003) and APO Productivity Database suggest an inverse relationship between these two ratios (Figure B3). Countries with a low GFCF ratio tend to be those with high per capita GDP, and the observed data suggest that information technology tends to play a more

important role in these countries than in the less developed countries. Furthermore, it is observed from the OECD and APO software data that the software investment ratio has been gradually increasing over the past 25 years.

We apply this inverse relationship between these two ratios observed from the OECD countries to estimate the software investment to GDP ratio in 2006 for those APO member countries which do not capitalize software investment. The estimated ratios for individual countries in 2006 are gradually tapered off as we move back in time. However, there is an exception. Countries at the very early stage of economic growth are found to have a GFCF ratio as low as countries with high per capita GDP, but for a different reason. The low GFCF ratio is explained by the fact that these countries have not experienced economic development yet, and in turn this does not imply an important role for software investment. In this report, we regard Cambodia, Lao PDR and Nepal as countries at the very early stage of economic development, and assign Vietnam's software investment ratio, which is the lowest of all APO member countries, to these countries.

Another problem arises from partial software capitalization. There are three types of software: custom software, pre-packaged software and own-account software. Countries may have capitalized one or two types of software, but software investment data are often not available separately. We attempt to adjust for the varied level of capitalization across countries by adding the type of software which was not capitalized to countries' GDP. In the case of Japan's own-account software and ownership transfer cost, we used estimates (by Koji Nomura based on the US methodology by the Bureau of Economic Analysis) and added these to the GDP of Japan's software industry and GFCF.

Figure B3: Software Investment Ratio and GFCF Ratio to GDP

Figure 1: Current PPP-GDP, 1970–2006: Relative to the US

Figure 1 traces the time path of the changes in the size of the EU15, APO20 and Asia21 relative to the US (= 100) since 1970.⁹ Over the past three decades the APO20 has been expanding in its relative size, from a low base of just under 59.3 per cent of the US economy in 1970 to roughly the same size (96.6 per cent) in 2006. Progress was put back by the impact of the Asian financial crisis in 1997–1998, as can be clearly seen in the chart. It took the APO20 as a country group nearly a decade to recover the lost ground and return to its peak before the dip in the late 1990s in terms of its relative size to the US. While the APO20 has been expanding, the EU15 has been experiencing a relative decline in economic size over the same period, from 116.9 per cent of the US economy in 1970 to 94.8 per cent in 2006. The difference in fortunes for the two regions is made more pronounced when China is included in the Asian group. In Figure 1 we can clearly see the impact of China, with its recent impressive growth performance, which accounts for most of the acceleration in the Asian group's overtaking process from around 1990 to 2006. The size of this region's economy is now around 46.1 per cent bigger than the US economy.

Between 2000 and 2006 economic growth in the Asian economy based on PPP-GDP was 3.2 per cent, faster than in the US economy on average per year (2.4 per cent); 64 per cent of this was accounted for by China, as shown in Figure 2. This was

followed by India, contributing 21 per cent to the region's relative expansion. Those countries which had been hardest hit by the Asian financial crisis in 1997–1998 recovered from the recession and showed positive contributions to the regional relative economic growth. During the 2000–2006 period Japan was the only economy in the Asia-Pacific region to grow more slowly than the US, as reflected in its negative contribution to regional relative growth. Although the Japanese economy eventually did escape from its long recession in the late 1990s, the speed of recovery has been very modest.

Table 3 presents the cross-country comparisons of economic growth in Asia in three recent periods: 1990–1995, 1995–2000 and 2000–2006. During the latter half of the 1990s growth slowed across the Asian countries. The region's growth was 4.2 per cent per year on average in the period 1995–2000, compared with 5.3 per cent in the previous period, reflecting the impact of the Asian financial crisis in 1997–1998. The ASEAN8 were hard hit, with average annual growth slowing from 7.4 per cent in 1990–1995 to 2.5 per cent in 1995–2000. In contrast, growth in the US and EU15 accelerated from 2.4 per cent to 4.0 per cent and from 1.6 per cent to 2.8 per cent respectively. In the latest period of 2000–2006, however, the Asian economy recovered and achieved an average annual growth of 5.6 per cent, while growth in the US and Europe slowed to 2.4 per cent and 1.9 per cent respectively.

⁹ As described in Box 1, PPP estimates have been revised upward for most of the APO member countries. The revisions have the

impact of reducing PPP-GDP for the APO20 and Asia21, compared with the estimates in *Databook 2008* (APO, 2008).

Unit: Average annual growth rate (percentage)

Figure 3: Country Contributions to Asian Economic Growth

Within the Asian region the performance was again dominated by China, which achieved spectacular growth of 11.6 per cent, 8.3 per cent and 9.4 per cent on average per annum in the periods 1990–1995, 1995–2000 and 2000–2006 respectively. This, combined with its size, meant it contributed just under 50 per cent of the region's growth in the past decade, as shown in Figure 3. India's contribution accounted for 17 per cent of the region's growth in the latter two periods. China and India have clearly been driving the regional economy over the past decade. Although there were faster-growing economies than India, such as Cambodia and Vietnam, they were too small in size to make a significant impact on the region's economic growth. In contrast, Japan's performance was lackluster when compared to the region's vibrant growth, but due to its size Japan's contribution was similar to Korea's, at around 7.4 per cent (see Figure 3).

3.2 Catching Up in Per Capita GDP

Asia is a populous region. China and India alone account for more than one-third of the world's

population. Performance comparisons based on whole-economy GDP do not take into account the population size and can in turn exaggerate the well-being of countries with large populations. Per capita PPP-GDP (hereafter per capita GDP), which adjusts for differences in the population size, is more commonly used for international comparisons of performance. Even so, it is not without its shortcomings as a welfare measure. To have a balanced interpretation of the statistics, it is important to keep the limitations in mind (see Box 4).

Figure 4 shows how countries compare on the per capita GDP measure. Countries' per capita GDP levels appear to correlate with the age profile of the population (see Box 5). Since the measure is based on PPPs, the comparisons are affected by the recent PPP revisions, as discussed in Box 1. Consequently, the differences in results between *Databook 2008* and this edition stem not only from the fact that data for 2006 instead of 2005 are used, but also from the PPP revisions. Given the extent of the revisions, our view of cross-country relative performance is significantly altered.

Our latest results tell the outcome of the dramatic development effort made by the four Asian Tigers.¹⁰

10 The Asian Tigers are Singapore, Korea, the ROC and Hong Kong.

Figure 4: Per Capita PPP-GDP in 2006

With the exception of Japan, they occupy the top rankings among the Asian countries. According to the latest figures, not only has Singapore caught up with the US, but it has overtaken the US per capita GDP level since 2004 and surpassed it by 9.6 per cent in 2006. Hong Kong follows close behind, at 90.5 per cent of the US level. Japan's per capita GDP level, at 74.6 per cent of the US level or around two-thirds of the group leader, Singapore, is similar to that of the EU15. The ROC and Korea trail at 62.4 per cent and 52 per cent of the US level respectively. The relative performance of China and India, the two most populous countries in the world, is pulled down on this measure due to their population size, with their per capita GDP at 11.3 per cent and 5.7 per cent that of the US in 2006. Even so, this should not tarnish their remarkable achievement and progress over the past decade or so, especially for China, whose per capita GDP was only 2 per cent that of the US in 1980. The per capita GDP level of Asia21 as a group including China is 12.2 per cent that of the US. Excluding China slightly improves the reading to 12.8 per cent for the APO20. Thus the income gaps between the US and the majority of the Asian countries are still sizeable, indicating that there is still a lot of room to catch up. The gap is even starker if compared with the region's leader, Singapore.

Table 4 shows the cross-country comparisons by per capita GDP in 1980, 2000, 2005 and 2006. The

new data for 2006 bring little change to the cross-country comparisons when compared with 2005, except to confirm that China continued to gain strength in its relative position, eroding the prominence of Japan, the US and EU15. Japan's per capita GDP used to top the Asian countries until it was overtaken by Singapore in 1993. Singapore has also achieved what Japan has not managed, i.e. overtaking the US on the per capita GDP measure in 2004. The snapshot comparisons in Table 4 suggest that Japan's per capita GDP relative to the US has been fairly stable over the past quarter of a century, hovering around 75 per cent. Yet this masks the fact that Japan continued its catching-up process with the US up to 1991, reaching a per capita GDP level equivalent to 87.4 per cent of the US level before starting declining to the current level (Figure 5).

The rise of the Asian Tigers is evident in Table 4. Based on their per capita GDP levels in 1980, the Tigers fall into two natural groups: Singapore and Hong Kong at 58.6 per cent and 55.1 per cent that of the US respectively, and the ROC and Korea at 27.1 per cent and 21.4 per cent respectively. By 2006 the income levels had leapt to 109.6 per cent, 90.5 per cent, 56.9 per cent and 47.4 per cent that of the US for Singapore, Hong Kong, the ROC and Korea respectively, as a result of their remarkable development efforts. China is another country which has made commendable effort, raising its per capita GDP

Table 4: Cross-country Comparisons of Per Capita PPP-GDP in 1980, 2000, 2005 and 2006

Unit: US dollars at current market prices

from 2.1 per cent to 11.3 per cent that of the US between 1980 and 2006. In comparison, India's progress is much slower, with an income level rising from 3.4 per cent to 5.7 per cent over the same period. The decline of the EU15 in relative per capita GDP against the Asian leader is also evident from Table 4.

As noted in Box 4, a rise in the per capita GDP data does not always directly translate into an improvement in the welfare of the people concerned. In fact, as an average measure, per capita GDP can bear little relevance to individuals' personal experience if, for example, the distribution of economic gain is highly skewed or economic advancement has been achieved at high environmental and health costs which are not accounted for in the statistics. There are a lot more attributes to individuals' welfare than captured in one simple measure called per capita GDP. Supplementary statistics are therefore necessary

in order to build a fuller picture of progress made in individual well-being. Figure 5 plots Asian countries' per capita GDP relative to the US for the period 1970–2006. It shows that the APO20 as a group has achieved little in terms of catching up with the US, with its relative per capita GDP edging up only marginally from 10.6 per cent to 12.8 per cent of the US level in the past three-and-a-half decades. Including China has the effect of pulling the average per capita GDP down, but Asia21 as a group made a bigger leap from 6.9 per cent to 12.2 per cent over the same period. Yet the group performance conceals the interesting dynamics of individual countries in the region. Japan started its catching up much earlier than other countries in Asia. By 1970 Japan's per capita GDP was 66.5 per cent that of the US. It managed to close the gap with the US up to 1991. The gap widened again when the impact of the long recession of the 1990s started to manifest itself.¹¹

Figure 5: Per Capita Current PPP-GDP, 1970–2006, Relative to the US

A similar process was seen taking place among the four Asian Tigers, which have managed impressive growth for the past four decades and have been aggressively closing the per capita GDP gap with the US. In 1970 Hong Kong and Singapore had similar per capita GDP, at around 36 per cent that of the US. By 2006 Singapore had surpassed the US and Hong Kong was at 90.5 per cent of the US level, bypassing Japan on the way. During this time their progress was only seriously frustrated once, by the Asian financial crisis of 1997–1998. Thereafter, they bounced back strongly. Per capita GDP has also been rising in the ROC and Korea, from around 16 per cent in 1970 to 62.4 per cent and 52 per cent relative to the US in 2006 respectively. The remarkable performance of the Asian Tigers has set them apart from other developing economies that were comparable in the 1960s. Because of its potential policy significance, the “Asian miracle” has generated vigorous research to establish the underlying factors in this sustained economic success. For a summary of the debate, see Box 6.

China’s progress in recent years is also noticeable. Its per capita GDP relative to the US has increased from a very low level of 1.7 per cent in 1970 to 11.3 per cent in 2006. Only time will tell if this marks the start of a phenomenal economic trend. India’s progress was less impressive in comparison; its relative per capita GDP rose from 3.9 per cent in 1970 to 5.7 per cent in 2006, allowing China to surge ahead from the early 1990s.

Catching up to the per capita GDP level of the advanced economies is a long-term process that could take several decades to accomplish. Empirical evidence has suggested that there may be a negative correlation between per capita GDP level and the speed of catching up, although not without exceptions. With the possibility of adopting successful practices and technologies from the more advanced economies, less advanced economies are poised to experience faster growth in per capita GDP, enabling them to catch up in average income level. However, as their income levels come closer to those of the more advanced countries, their economic growth

11 Jorgenson and Nomura (2007) found that the levels of Japan’s per capita GDP and total factor productivity (TFP) in 1960 were only 25.5 per cent and 52.4 per cent those of the US, respectively. They also indicate that the manufacturing

sector was the main contributor to the catching-up process of the Japanese economy in the 1960s, and that the US–Japan TFP gap for the manufacturing sector had almost disappeared by 1990.

Box 4: Limitations of Per Capita GDP as a Welfare Measure

GDP is an aggregate measure of production within the boundary of an economy, and is not intended to be a welfare indicator. Key factors that have significant bearing on individuals' well-being are omitted. Even though GDP per capita has corrected for the size of population, it still suffers from serious limitations as it inherits the inadequacies of GDP as a welfare measure.

Net domestic product

GDP is a gross concept and hence does not take into account depreciation of capital goods. The larger the amount a society needs to set aside to renew its capital stock, the less is made available for consumption; in turn, other things being equal, the lower will be individuals' current level of well-being. Net domestic product (NDP) is therefore more informative than GDP in judging the well-being of a society. However, due to the difficulty in estimating depreciation, GDP remains more readily available and in turn more widely used than NDP, particularly in international comparisons.

Gross national income

Income generated domestically may be remitted abroad, and profits accrued to foreign-owned firms do not enhance the spending power of the nationals. Similarly, local residents may also receive income and dividends from abroad. After adjusting GDP for these international transfers, the resulting income measure is gross national income (GNI). With globalization and the shift from manufacturing to services, the differences between GDP and GNI have increased.

Real income

Real income is GDP adjusted for the effects of changes in terms of trade, which is the relative price of a country's exports to imports. If exports prices are rising relative to imports, a country is better off because it has access to more imports without the need of increased exports, and vice versa. Currently, an increasing number of researchers are analyzing the sources of real income growth in several countries, such as Australia, Canada and Japan. They found that the terms-of-trade effect was relatively small in these countries over a long period of time, but its impact could be more significant over a shorter period when there were large fluctuations in a country's terms of trade, for example those induced by the oil shocks. Chapter 5 overviews the trend of real income across Asian countries.

"Green" GDP

Standard GDP does not take into account degradation of the environment and depletion of natural resources, the importance of which has been rising with people's awareness. To address this shortcoming, proposals have been made towards a concept of "green" GDP which corrects for the degradation of natural resources. A more comprehensive response, in which national accountants have played an active

part, is an ambitious statistical framework, known as the System of Integrated Environmental and Economic Accounting (SEEA). Despite the progress already made, no single measure or set of indicators has yet been established as the international standard to date.

Actual individual consumption

Individual well-being is determined more by the consumption level than the income level. In many countries, households obtain goods and services not only through market purchases but also as transfers in kind or at greatly reduced prices from the government. Actual individual consumption is defined in the official national accounts as the total value of household final consumption expenditure, expenditures by non-profit institutions serving households (such as non-governmental organizations and charities) and government expenditure on individual consumption goods and services (such as education and health). This definition helps minimize the effect of differences in institutional arrangements on the volume comparisons of individual well-being. The World Bank (2008), for example, estimates that actual individual consumption constitutes 69 per cent of GDP on average across countries. However, consumer shares are found to be lower and investment shares higher in Asia-Pacific countries and Western Asian regions.

Income distribution

Underlying GDP per capita is an assumption of an equal distribution of income. When income distribution is highly skewed or is rising, an average measure like GDP per capita is losing its relevance to the population that it seeks to represent. One way of measuring this skew is to compare the average with median income – the income such that half of the population is above that income, half below. Increasing differences between the two income measures imply a rise in inequality, and the "typical" income level as measured by the average income is losing its representativeness for the population. Instead, more attention should be directed to understanding the characteristics and income level of different demographic groups. Groups can be differentiated by their income level, regions, ethnicity, occupation or age, to name just a few. By tracking the rate of income change in each group, we can trace if inequality has worsened over time.

There is no doubt that the gap between our welfare concerns today and what are being captured in the GDP-related measures has widened. The international professional community has been making a concerted effort to find the best feasible ways to address the issues raised (see Stiglitz, Sen and Fitoussi, 2008). While we wait for better measures to be established, we have to rely on the existing statistics to shed light on our current situation, however imperfect they are. To ensure a balanced interpretation, however, it is worth keeping their limitations in mind.

Box 5: Population of Asian Countries

According to the UN Population Database (UNPD), the world's population was estimated at 6.5 billion in 2005, of which Asian countries accounted for 60.4 per cent. The region is by far the most populous in the world. China and India account for 20.2 per cent and 17.4 per cent of the world's population, respectively. Countries covered in this report, excluding Fiji which, according to the UNPD, belongs to the Oceania region, make up just over 90 per cent of the Asian population.

Figure B5 shows the proportions of the under-15 and over-65 age groups, which together make up the dependent population, in each country in 2006. In Japan, where one in five persons is over 65, the extent of the aging population is evident. This is in contrast with the averages of 6.0 per cent and 6.6 per cent respectively for the APO20 and Asia 21 (i.e. including China). Japan is also the country where the ratio of working population to the over-65 population, at 3.3, is the lowest among the countries studied in this report. The corresponding figures for the APO20 and Asia21 are 10.6 and 10.0 respectively.

It is not surprising to note that countries which have the highest per capita GDP in Asia (Figure 4) are also those which have relatively the largest working population. Coinci-

dentally, they are also the countries which have the highest population shares of the aged and lowest for the under-15 population. Relatively, Japan has by far the largest population of over-65s among countries compared. In contrast, countries which have the lowest per capita GDP are those with a relatively large youth population. This may reflect a negative correlation between individuals' income level and the fertility rate. The population share of the under-15s varies from 14 per cent in Japan to around 40 per cent in the low-income countries. These figures compare with the Asian averages of 27.1 per cent and 30.6 per cent for Asia21 and the APO20 respectively. The ratio of working population to the under-15 population ranges from a high of 5.0 in Hong Kong to a low of 1.5 in Lao PDR and Nepal.

The four Asian Tigers plus China and Thailand have a dependent population (under-15s and over-65s) of just under 30 per cent of the total population, giving a ratio of working population to dependents of 2.5 to 2.7, well above the Asian averages of 2.0 and 1.7 for Asia21 and APO20 respectively. The ratio is 1.9 for Japan, 1.7 for India and drops to 1.4 for Nepal and Lao PDR, where the youth population is most prominent.

Figure B5: Population Proportion of the Dependent Population (Below 15 and Over 65 Years of Age), 2006

rates are expected to decline over time.¹²

Table 5 summarizes the relationship between economic level and the speed of catching up in Asian countries. Economic level is measured by a country's real per capita GDP relative to the US at the start of

the series, i.e. 1970, or from whichever year the data first became available for the individual country under concern.¹³ Countries are grouped according to their per capita GDP level: Group-L1 with per capita GDP at or above 60 per cent of the US; Group-L2,

12 The OECD (2008) observes that GDP per capita has broadly converged in the OECD countries since the 1970s. But more advanced economies that started with high income levels in the 1970s have had lower rates of catch-up, or even

stagnated or recently diverged *vis-à-vis* the US. Between 1973 and 2006 Ireland and Korea managed the highest rates of catch-up in per capita GDP, with 2.3 per cent and 3.8 per cent per year respectively.

Table 5: Country Groups Based on the Initial Economic Level and the Pace of Catching Up with the US

GDP Level to the US	Annual Rate to Catch Up to the US			
	(C1) 2% <	(C2) 0.5% < - < 2%	(C3) -0.5% < - < 0.5%	(C4) < -0.5%
(L1) 60% <			Japan, EU15	
(L2) 20% < - < 60%	Hong Kong, Singapore			Iran
(L3) 5% < - < 20%	Korea, ROC, Thailand	Malaysia	Mongolia	Fiji, Philippines
(L4) < 5%	Cambodia, Indonesia, Vietnam, China	India, Sri Lanka, Lao PDR	Bangladesh, Nepal, Pakistan	

The annual catch-up rates are estimated based on the data during 1970–2006. (The initial observation periods are different for some countries due to data availability.)

The GDP level is defined as a ratio of per capita PPP-GDP between each country and the US at the start of the data series for each individual country.

**Figure 6: Labor Productivity and Employment Rate Gap with Respect to the US, 2006**

from 20 per cent to under 60 per cent; Group-L3, from under 5 per cent to under 20 per cent; and Group-L4, below 5 per cent. Likewise, countries are also grouped according to the speed of their catch-up with the US: Group-C1, at 2 per cent per annum or above; Group-C2, from 0.5 per cent to under 2 per cent; Group-C3, from -0.5 per cent to under 0.5 per cent; and Group-C4, under -0.5 per cent.

From Table 5 we can see that economic level does not fully explain the catch-up process. Of the 21 Asian countries, nine achieved very fast catch-up, i.e. over 2 per cent a year on average between the respective starting years of their data series and 2006. However, their per capita GDP level ranges from 1.7 per cent (China) to around 36 per cent (Singapore and Hong Kong) of the US level in 1970. Three of the

lowest-income countries, namely Bangladesh, Nepal and Pakistan, have failed to achieve much catch-up. Three countries, Iran, the Philippines and Fiji, experienced deterioration in their relative income level against the US, and are in Group-L2 and Group-L3 respectively. Japan was the only Asian country with a high-income level in 1970. But, like the EU15, Japan has failed to achieve further catch-up with the US since then.

To understand the diverse performance in the Asian group further, per capita GDP can be broken into two components, namely labor productivity (defined as PPP-GDP per worker in this report) and the corresponding labor utilization rate (i.e. number of workers to population ratio, or the employment rate in this report). Figure 6 shows the percentage

13 For most countries the starting year is 1970. Others have different starting years due to data availability constraints: Bangladesh (1973), Cambodia (1993), Fiji (1975), Lao PDR

(1984), Malaysia (1975), Mongolia (1982), Nepal (1984), Pakistan (1971) and Vietnam (1986).

Figure 7: Sources of Per Capita GDP Growth, 1995–2000

Figure 8: Sources of Per Capita GDP Growth, 2000–2006

point difference in per capita GDP decomposed into the contributions by the labor productivity gap and the employment rate gap with respect to the US in 2006. Most of the Asian countries display a huge per capita GDP gap with the US, which is predominantly explained by their relative labor productivity performance. Except for the four Asian Tigers, Japan and Iran, all the other Asian countries have a labor productivity gap of more than 60 per cent against the US. Singapore is the only country which has effectively closed the labor productivity gap with the US: a 3.2 per cent difference is statistically insignificant. Hong Kong still has a gap of 12.5 per cent, the ROC 30.6 per cent and Korea 47.3 per cent against the US.

Most countries also have an employment rate short of the US level, substantially in the case of Iran,

Malaysia, Pakistan and Bangladesh, further reinforcing their poor productivity performance. Notwithstanding, a handful of countries, i.e. China, Cambodia, Thailand, Singapore and marginally Japan, Vietnam and Hong Kong, had higher employment rates than the US, counteracting the negative impact of their productivity performances. In particular, the positive gap in employment rate plays a significant role in nudging Singapore ahead of the US in per capita GDP. In Chapter 6 we take a closer look at the time profiles of these two variables relative to the US.

Figures 7 and 8 focus on explaining a country's per capita GDP growth by its components: namely labor productivity and the change in the employment rate for the periods 1995–2000 and 2000–2006, respectively.¹⁴ For most countries in Asia the majority of per capita GDP growth can be explained by

Box 6: What Drives Growth in Asia: Accumulation or Assimilation?

Since the 1960s a handful of East Asian economies, notably Singapore, the ROC, Hong Kong and Korea, have managed to set themselves off on a path of impressive growth. With their real per capita GDP growing at a pace of 4–5 per cent per year on average, these economies have outperformed other developing countries that were comparable in the 1960s, and stand out as the only region that has managed to catch up to the living standards of the advanced countries. Figure 5 shows how these economies rapidly closed the per capita income gap with the US from 1975, against the background of little progress made by the region as a whole. Because of its potential policy significance, the recipe for the “Asian Miracle” has been a subject of vigorous academic debate.

Among other views, narrowing the “idea gap” was put forward as an explanation by Romer (1993). He argued that underlying the success of the East Asian economies was their ability to adopt existing technologies from the advanced economies. If true, this represents a less costly approach to economic development than the accumulation view, whereby the road to prosperity is through savings and investment, i.e. forgone current consumption, which many poor countries cannot easily afford.

Empirical evidence, however, has lent little support for this view. East Asia’s rapid growth has been found to be largely driven by factor accumulation, with total factor productivity (TFP) growth accounting for only one-quarter of the region’s growth in labor productivity between 1960 and 1994 (Collins and Bosworth, 1996). The main lessons from East Asia’s success are therefore not about which policies best promote TFP growth. Rather, the focus should be on how to achieve and sustain high rates of savings and investment, defying the law of diminishing returns.

With an investment ratio of over 20 per cent of GDP, Nelson and Pack (1999) argued that the success of the fast-growing Asian economies lay in their extraordinary ability to absorb and assimilate technologies superior to their own at a rapid pace sustained over a long period without slowing. This process involved uncertainty and economic risk in an essential way. To sow the seeds of success, a favorable policy environment was first required to nurture learning, innovation and entrepreneurship. Subsequently it was the shift of resources into the more modern, capital-intensive

technologies, through aggressive entrepreneurship and progressive learning that held the key to sustaining high rates of return on capital and in turn investment, which drove growth. In other words, the observed dramatic shift in the product mix and firm size in these Asian economies should be seen as an integral part of their success story, which ran far deeper than simply factor accumulations.

Empirically, assimilation rates vary across countries, resulting in diverse development experience and outcomes. Focusing on level comparisons of Asian and US manufacturing for the period 1963–1997, Timmer (2002) observed that labor productivity levels achieved by the ROC and Korea in 1997, even after a period of capital intensification, were lower than what the US had achieved at similar levels of capital intensity. In other words, capital accumulation might have created the potential but was not itself a sufficient condition for performance; the same amount of capital was used more productively in the US in the 1970s and 1980s than in Korea and the ROC in the 1990s. The US’s superior assimilation ability was also apparent in comparisons with Europe. The divergent productivity performance in the latter half of the 1990s was largely attributed to the failure of Europe to reap productivity gains from its ICT investments compared with the US (see for example O’Mahony and van Ark, 2003). Empirical evidence therefore suggests that soft investment in organizational change, managerial skills and human capital is required to complement the accumulation effort.

Given the diminishing possibilities for further productivity improvements with a particular technology, sustained growth must involve the continual introduction of new technology, new goods and new activities. However, the pace of the climb up the technological ladder can be too fast if insufficient time is allowed for the assimilation process, and learning costs are too high to be beneficial to productivity growth. On the other hand, countries can also be stagnant in productivity growth with existing technology when the pace of technological change is too slow and new opportunities are not created. The right balance is difficult to judge a priori, and different industry sectors even within a country can display diverse capabilities in adopting new technologies and pushing the frontier. In general, flexibility of a country in resource allocation and factor markets with a well-educated workforce will be conducive to the process.

labor productivity, but this should not lead us to underestimate the role played by changes in the employment rate. On average, Asian countries’ per capita GDP (excluding Lao PDR) grew by 2.7 per cent a year between 1995 and 2000, and accelerated to 3.6 per cent a year between 2000 and 2006. The earlier period captured the dampening effect of

the Asian financial crisis of the late 1990s. Emerging from the crisis, both labor productivity growth and employment growth strengthened. For most countries, labor productivity explains a larger share of per capita GDP growth than employment. Pakistan and Fiji are the two exceptions, where employment rate accounts for a larger proportion of their per

14 Lao PDR is omitted from Figures 7 and 8 due to data issues.

capita GDP growth than labor productivity in both periods, but this should not lead us to underestimate the importance of rising labor productivity in these economies. Between 2000 and 2006 the employment rate contribution was highly significant in Cambodia (45 per cent), Mongolia (50 per cent), Thailand (34 per cent), Sri Lanka (37 per cent), Korea (25 per cent), Bangladesh (37 per cent) and the Philippines (35 per cent).

China's improvement was the most impressive, achieving per capita GDP growth of 7.3 per cent and 8.7 per cent a year on average in the two periods

respectively. In recent years 96.2 per cent of that growth was explained by labor productivity, reflecting a much stronger growth in labor productivity than in the employment rate. Between 2000 and 2006 Mongolia, Pakistan, Iran and Fiji have the employment rate accounting for half or more of the per capita income growth. Japan had a worsening employment rate in both periods. With an aging population (see Box 5), this pattern may well persist. To sustain per capita GDP growth, labor productivity growth will have to accelerate in order to counteract the negative effect of its employment rate.

4. Decomposition of GDP Growth by Expenditure Category

GDP can be decomposed according to expenditure on final demand, and income to factor inputs or production (i.e. into industry or products). These decompositions are valuable in understanding the structure of an economy, and in turn how it will react to a given economic shock. As the global economy is heavily battered in the current storm originating from the global financial crisis, a structural analysis of the Asian economies can help us assess their ability to weather the storm. In this chapter we look at countries' economic composition from the expenditure side, while their industry structure is presented and analyzed in Chapter 7.

4.1 Final Demand Composition

The Asian regional economy and the three reference economies are very different in their economic structures. With the different emphasis and vulnerabilities, their behavior and reaction to economic shocks can be expected to be quite diverse. Table 6 presents comparisons of final demand shares of nominal PPP-GDP. GDP is decomposed into four categories of final demand: household consumption (including consumption of non-profit institutions serving households), government consumption, investment

(or, in national accounts' terminology, gross fixed capital formation (GFCF) plus changes in inventories) and net exports (i.e. exports minus imports).

With the exception of China, household consumption is by far the biggest component of GDP in an economy. Over the past decade household consumption share in APO countries has not expanded noticeably despite the rise in income, hovering around 55–58 per cent. The inclusion of China pulls down the group average, and the share for Asia21 contracted from 54.8 per cent to 50.5 per cent between 2000 and 2006. China saw a huge drop in household consumption as a share of GDP, from 46.4 per cent in 2000 to 36.3 per cent in 2006. This suggests that growth of household consumption in China has been falling behind its economic growth at current prices. India, another fast-emerging economy, has held its household consumption share stable at around 60 per cent in the past decade (see Figure 11). In contrast, share of household consumption has been rising consistently in the US, from 66.9 per cent of GDP in 1995 to 68.2 per cent in 2000 and 69.5 per cent in 2006. The share of household consumption in the EU15, which is in the upper 50 per cent range, has stayed slightly higher than the Asian average and has been relatively stable over the past decade (Table 6). Given the relatively low propensity of Asian households to consume, fiscal stimulus will have a

Table 6: Comparisons of Final Demand Shares in GDP in 1995, 2000 and 2006

		Household consumption	Government consumption	Investment	Net exports
1995	Asia21	54.0	12.8	32.9	0.3
	APO20	56.5	12.6	30.9	0.0
	China	44.9	13.3	40.3	1.6
	US	66.9	15.5	18.9	-1.3
	EU15	58.2	20.3	20.1	1.4
2000	Asia21	54.8	14.1	28.5	2.5
	APO20	57.7	13.5	26.2	2.6
	China	46.4	15.9	35.3	2.4
	US	68.2	14.6	21.2	-4.0
	EU15	58.6	19.8	21.3	0.3
2006	Asia21	50.5	13.4	21.3	3.7
	APO20	57.7	13.3	27.2	1.8
	China	36.3	13.7	42.6	7.4
	US	69.5	16.0	20.4	-5.9
	EU15	57.8	20.7	21.0	0.4

Unit: GDP share (percentage)

role to play in generating enough domestic demand to bolster local economies as well as the world economy in a time of retrenchment.

The lower share of household consumption in the EU15 has been offset by a larger share of government consumption, which accounts for around 20 per cent of its nominal GDP. This compares with 13–14 per cent in Asia and 14–16 per cent in the US. The APO20 on average invests a lot more than the US or EU15, and has been sustaining an investment share in the region of the upper 20s to 30 per cent of GDP. The inclusion of China had the effect of pulling up the Asian average from 27.2 per cent to 32.4 per cent in 2006. This compares with a relatively stable share of around 20 per cent in the US and EU15. The share of investment in China is phenomenal, at 42.6 per cent in 2006, and has overtaken household consumption as the biggest final demand component of GDP since 2004.

Net exports are gaining weight in the Asian economy, rising from 0.3 per cent of GDP in 1995 to 3.7 per cent in 2006. China explained most of the strengthening between 2000 and 2006, with a net export share of 7.4 per cent in 2006, up from 2.4 per cent in 2000. In contrast, the deficit between exports and imports has more than quadrupled in the US, from 1.3 per cent of GDP in 1995 to 5.9 per cent in 2006. In the EU15 net exports have been a positive component, but have shrunk from 1.4 per cent in 1995 to 0.4 per cent in 2006.

Figure 9 shows the cross-country comparisons of final demand shares in current-price GDP in 1995, 2000 and 2006. The charts are ranked by the share of household consumption, the range of which is trending downwards among this group of countries. Cambodia has the highest household consumption share in Asia, which has fallen from 94.8 per cent of GDP in 1995 to 81.1 per cent in 2006. Singapore used to be the Asian economy with the smallest household consumption share, but since 2001 China has replaced Singapore in that position, with a share of 36.3 per cent in 2006. A deficit in net exports tends to be associated with high household consumption, and refraining from consumption is required to support high investment levels. Countries with low income, however, may struggle to defer consumption in order to invest. In 2006 only Cambodia, Bangladesh and Nepal¹⁵ remained in the bottom income group among the countries studied in this report (see Table 10). It is not a coincidence that these are

also the countries which have the highest household consumption share in Asia. Net exports carry a particularly large weight in a handful of economies: in 2006 it was 29.8 per cent in Singapore, 22.9 per cent in Malaysia and 11.4 per cent in Hong Kong, reflecting their entrepôt function in Asia. This explains why the total values of exports and imports are exceptionally high relative to the size of GDP in these economies (Figure 10).

Figure 11 shows the long-term trends of household consumption share of GDP for selected Asian countries. The Asian Tigers have been the high performers, and come top in most of the level indicators presented in Chapter 3. As seen in Figure 11.1, all four Asian Tigers experienced an initial relative retrenchment in household consumption as a share of GDP in their development process. Since the late 1980s, however, the trend of retrenchment has been either reversed (in the ROC) or slowed (in the other three Tigers). Taking the whole period together, the share in Singapore fell from 69.7 per cent of GDP in 1970 to 38.9 per cent in 2006, from 74.6 per cent to 53.4 per cent in Korea and from 64.8 per cent to 58.6 per cent in Hong Kong. The ROC is the only exception, where the reversal of the downward trend was so strong that the household consumption share was higher in 2006 than in 1970 (i.e. 58.9 per cent compared with 55.1 per cent).

Figure 11.2 plots the trends of household consumption in the three largest Asian economies by size. The downward long-term trend in India and China is unmistakable. When GDP is growing faster than consumption, the share of the latter in GDP will diminish. With recent rapid growth in these economies, people's spending habits might not have caught up with the recent success. Given that the poor tend to have a higher propensity to spend than the rich, the falling share of household consumption may partly reflect the very uneven distribution of economic gain in these countries. Furthermore, the fact that China has a dependent population of 29 per cent compared with 37.5 per cent in India (Box 5) may help explain why India has to sustain a much higher share of household consumption than China despite its falling trend over time. In contrast, the household consumption share in Japan has been rising slowly since 1970, from just under 48.5 per cent to 56.6 per cent in 2006. With a rapidly aging population (Box 5), this rising trend can be expected to continue in Japan.

¹⁵ Lao PDR is also in the bottom income group; it is, however, omitted from Figure 9.

Figure 9: Cross-country Comparisons of Final Demand Shares in GDP

Relative to the US, however, Asians spend a lot less in proportion (Figure 11.3). Household consumption in the US accounted for nearly 70 per cent of its GDP in 2006, rising from a level of 62 per cent in 1970. The share of household consumption in the EU15 is more comparable to the Asian average level, fluctuating within a tight range between 56 per cent and 60 per cent of GDP in the past three decades.¹⁶

Figure 12 looks at the long-term trend of investment share in GDP across countries. Figure 12.1 plots the trends for the Asian Tigers, which have experienced rapid catch-up with the US in per capita GDP since the 1960s. In the 1970s their investment share of GDP ranged from 20 per cent to 40 per cent; in the early 1980s the share in Singapore even approached 50 per cent. More recently, however, investment

Figure 10: Cross-country Comparisons of Export and Import Shares in GDP, 2006

Figure 11: Long-term Trend of Household Consumption Share in GDP, 1970–2006

shares generally have softened compared to their historical peaks, and vary between 20 per cent and 30 per cent among countries. Figure 12.2 plots the trends for the three largest Asian countries. It is clear that investment share is trending upward in both China and India, but at different levels. Investment share increased from 33.8 per cent in 1970 to 42.6 per cent in 2006 in China, and from 17.8 per cent to 33.0 per cent in India. In contrast, investment share in Japan has been falling, from 39.6 per cent in 1970 to 24.6 per cent in 2006.

Figure 12.3 shows the Asian group averages against the US and EU15. The chart confirms that Asian countries on average invest more, with their average investment share of GDP staying above the US and EU15 throughout the whole period. The averages for the APO20 and Asia21 moved closely to each other until the 2000s, when strong investment in China drives a wedge between the two group averages. Over the long run, a couple of cycles in investment can be spotted. Investment made up 32.3 per cent of GDP for the APO20 at the start of the period in 1970, but

16 It is worth noting that the GDP share of government consumption in the EU15 is 6 per cent higher than the average of Asia21 in 2006 (Table 6). In fact, when it comes to welfare measurement, actual individual consumption, as opposed to household consumption, is preferred because the

former takes into account expenditures by non-profit institutions serving households and government expenditure on individual consumption goods and services (such as education and health) in addition to household consumption. (For more details see Box 4.)

Figure 12: Long-term Trend of Investment Share in GDP, 1970–2006

by 1986 it fell to 26.4 per cent. Within four years investment bounced back to its 1970s' level from this trough, only to experience a subsequent decade of downward trend as a share of GDP, with a particularly sharp impact from the Asian financial crisis of the late 1990s. With the buffer provided by China, the average for Asia21 fell less than that of the APO20 in the late 1990s. Investment reached its lowest level in 2003, at 28.2 per cent for Asia21 in 2001 and 24.4 per cent for the APO20. Since then investment has started to pick up again in Asia, with Asia21 bouncing back much more strongly than the APO20, reaching 32.4 per cent of GDP in 2006 compared with the APO20's 27.1 per cent.

In the EU15 investment was 27.3 per cent of GDP at the start of the period, compared with 19.1 per cent for the US. Investment share in the EU15 had been on a downward trend, save a brief period in the late 1980s when it edged up. It fell to about 20 per cent of GDP in the late 1990s, converging with the US level. Since then investment share has been hovering around that level, in synch with the US. Throughout the period investment share in the US has been steady, teetering around 20 per cent of GDP.

Figure 13 plots the long-term trend of net export share in GDP from 1970 to 2006. Net exports used to be a drag on the Asian Tigers' GDP. In the early 1970s all the Tigers had huge negative net exports, except Hong Kong. But they rapidly improved on their position, and in recent years net exports are making a positive contribution to GDP in all Asian Tigers. The share of net exports in Singapore is particularly large, at 29.8 per cent in 2006, compared with 0.9 per cent, 5.9 per cent and 11.4 per cent for Korea, the ROC

and Hong Kong respectively. In contrast, net export shares for the three largest Asian economies fluctuate within a much smaller range over the years (Figure 13.2). All three countries started off from a position of balanced trade in 1970. Thereafter they branched out on three different paths. The balanced position turned into a mild trade deficit in India at the start of the 1980s, and has been stable ever since. In 2006 the share of net exports in GDP was -3.0 per cent in India. Japan has been running a small trade surplus, which peaked in the mid-1980s. In 2006 the share of net exports was 1.2 per cent in Japan. For China, after teetering around the balanced position for much of the period, a trade surplus has been established since the mid-1990s. The rise in its share in GDP had been particularly strong since 2004, but this trend can be expected to halt or even reverse in 2008–2009 as demand dries up from the rich economies; exports from China have fallen in recent months in the midst of the current storm in the global economy.

Figure 13.3 compares the average net export share for the APO20 and Asia21 with the US and EU15. Both the US and EU15 faced a trade deficit at the beginning of the period. While the EU15 managed to revert and has been in surplus since the early 1990s, the US has significantly deteriorated since 1990, after a tremendous effort in restoring its trade balance in the late 1980s. In 2006 the size of the US trade deficit stood at 5.9 per cent of its GDP. In contrast, the APO20 and Asia21 have been in surplus continuously since the early 1980s. In 2006 the average net export share for the APO20 was 1.8 per cent of GDP. The inclusion of China swings this up to 3.7 per cent.

Figure 13: Long-term Trend of Net Export Share in GDP, 1970–2006

4.2 Growth Decomposition by Expenditure Category

Figures 14 and 15 show the decomposition of the average annual economic growth by final demand for the periods 1995–2000 and 2000–2006 respectively.¹⁷ During the earlier period Asia was suffering from the Asian financial crisis, which appeared to hit investment particularly hard in Thailand and Indonesia. Investment fell by 14.1 per cent and 10.6 per cent on average in Thailand and Indonesia respectively, canceling out growth in other components of final demand and resulting in no overall economic growth. During this period, for most of the countries in Asia, the engine of growth had been household consumption. However, net exports were the real driving force in some economies, accounting for around 60 per cent of economic growth in Korea and Hong Kong, and 92.5 per cent in Malaysia, to counterbalance the fall in investment expenditure. They also made a significant contribution in Japan and the Philippines, accounting for 23.7 per cent and 27.1 per cent of the average economic growth per annum respectively. The US, EU15 and Sri Lanka were the only countries where net exports dragged down growth.

The impact of investment expenditure on economic growth was negative in five out of the 17 economies, as presented in Figure 14 (i.e. Malaysia,

Indonesia, Hong Kong, Japan and the Philippines), and marginally in Korea. But in other countries it made a significant contribution, accounting for 20–50 per cent of economic growth. During the period 1995–2000 China experienced the fastest economic growth among the countries studied, averaging 7.9 per cent per year,¹⁸ of which 46.1 per cent was contributed by household consumption, 17.3 per cent by government consumption, 28.0 per cent by investment and 8.6 per cent by net exports. This compares with an average annual growth of 3.9 per cent in the US and 2.8 per cent in the EU15. The contribution from household consumption was 73.6 per cent and 60.0 per cent in the US and EU15 respectively. During this period investment growth also played a significant role, accounting for 39.5 per cent and 32.6 per cent of growth in the US and EU15 respectively.

On the back of the Asian financial crisis, investment growth surged strongly: its impact on real GDP growth became more significant in Asia in the first half of the 2000s, and appeared to be a major driving force in the Asian economies (Figure 15). Countries which experienced the fastest economic growth were also countries where the contribution from investment growth was the largest in terms of percentage points: it was 5.3 per cent in China, 3.0 per cent, 3.6 per cent and 3.5 per cent in Cambodia, Vietnam and India respectively and 2.3 per cent in the Philippines. For Singapore, Hong Kong and the ROC, the strength

17 Lao PDR, Fiji and Mongolia are excluded from Figures 14 and 15, while Nepal is only excluded from Figure 14.

18 In this section, real GDP growth is calculated based on

Törnqvist's quantity index applying to the components of final demand. As a result, the real GDP growth may diverge from the official estimates or those presented in Table 3.

Figure 14: Final Demand Contributions to Average Annual Economic Growth, 1995–2000

Figure 15: Final Demand Contributions to Average Annual Economic Growth, 2000–2006

of net exports was the economic story, accounting for half to three-quarters of their economic growth on average per year between 2000 and 2006. The role played by net exports in China has also strengthened, with its contribution to economic growth doubling between the two periods. The reverse was true in India, where net exports swung from making a positive contribution of 3.1 per cent in the earlier period to being a drag on economic growth (–11.5 per cent) in the period 2000–2006. In some of these economies the contribution of household consumption to economic growth was really squeezed: for example, from 46 per cent in 1995–2000 to 25 per cent in 2000–2006 in China, from 43 per cent to 27 per cent in Singapore, from 45 per cent to 34 per cent in Hong Kong and from 60 per cent to 38 per cent in the ROC. Also, in the latter period, more Asian countries

ran a trade deficit, particularly Malaysia, Nepal, Sri Lanka and Iran.

In the first half of the 2000s economic growth slowed in both the US and the EU15: from 3.9 per cent on average per year to 2.4 per cent, and from 2.8 per cent to 1.9 per cent, respectively. In terms of contributions, household consumption increased from 73.6 per cent to 86.6 per cent and government spending from 6.5 per cent to 14.5 per cent in the US over the two periods. This suggested that household consumption did not retrench as the economy slowed, while the government increased spending to bolster the economy. Investment in the US, however, took a plunge, from a contribution share of 39.5 per cent to 15.3 per cent over the two periods. Net exports slightly improved from –19.6 per cent to –16.4 per cent. The EU15 had a similar pattern, where the

contribution of government spending nearly doubled over the two periods from 11.8 per cent to 21.9 per cent, squeezing out the contribution of investment by one-third, while household consumption remained more or less stable. Net exports also improved from -4.5 per cent to -0.4 per cent.

Figure 16 shows how the contribution of economic growth by final demand varies across countries and over time for the period 1970–2006. Economic restructuring is a gradual process and could take a long time to establish. Some shifting in the relative weight of the key drivers of growth may be emerging in some countries, and is discernible in our data covering the past three-and-a-half decades. Furthermore, the Asian financial crisis of 1997–1998 marked an exceptional time for many Asian economies. Its impact can clearly be seen in Indonesia, Korea, Malaysia, Singapore and Thailand, where investment took a nose-dive in 1998; consumption also fell, albeit to a lesser extent. By contrast, net export growth was exceptionally strong, and was likely to have benefited from the rapid devaluation of the Asian currencies at the time of crisis.¹⁹

Household consumption has been one key driver of economic growth in the Asian countries, but its importance varies across countries and across time. In the ROC and Hong Kong, for example, it bore a much larger weight at the beginning of the period, but in recent years the percentage contributed by household consumption has been much lower. Investment, on the one hand, has been a consistent and significant driver of economic growth in many Asian economies (notably in the four Asian Tigers, and more recently in China, India, Vietnam and Thailand); on the other hand, it has also contributed to the volatility of economies.

Net exports have been a significant driver in Asia, and subject to wider swings when compared to the US and EU15. In the ROC they were a key engine of

growth in the 1970s. In the latter half of the 1980s and the 1990s growth was mainly about household consumption and investment. Since the turn of the millennium, however, net exports have regained their importance as a driver of economic growth. Similarly, in the 2000s growth in Hong Kong has been mainly led by net exports, as has growth in Singapore barring 2004. The story in Korea has been about household consumption and investment; the role of net exports has not been firmly established. In contrast, net exports have emerged to play a more significant role in Japan's modest growth in the past five years.

For China, investment is clearly a key driver in the economy, and since the early 1990s it has often been the main contributor to economic growth. In recent years net exports have also emerged as being capable of making a positive contribution to growth. In contrast, the prominence of investment in India is less stark than in China, and net exports are still a drag on its growth effort. Government contribution to growth is also more consistent in China than in India.

For the US, household consumption as the key component of economic growth has never been challenged. Investment was strong and consistent for a decade in the 1990s, but contracted after the burst of the dot.com bubble at the turn of the millennium before recovering in recent years. Government fiscal stimulation can be clearly seen around this time. Since the early 1990s net exports have played a negligible role in US economic growth, if not being a drag on the economy. Like the US, economic growth in the EU15 is largely determined by its household consumption and investment. Net exports have not been making a significant contribution to growth in recent years. Growth of government consumption has been steady throughout the period, but efforts in restraint during the 1990s can clearly be seen before growth picked up again in the 2000s.

¹⁹ It appears that some Asian countries, for example the ROC, Hong Kong, Japan and Malaysia, also suffered adversely in 2001 following the burst of the dot.com bubble.

5. Real Income and Terms of Trade

The standard GDP concept does not adequately measure welfare, as discussed in Box 4. Among the shortcomings is its neglect of the terms-of-trade effect. Diewert and Morrison (1986) and Kohli (2004) point out that an improvement in the terms of trade (i.e. the relative prices of a country's exports to imports) unambiguously raises real income and welfare. In many ways a favorable change in the terms of trade is synonymous to technological progress, as it makes it possible to get more for less. That is, for a given trade-balance position, the country can either import more for what it exports, or export less for what it imports.

By focusing on production *per se*, the real GDP concept does not capture this beneficial effect of the improvement in the terms of trade. Kohli (ibid.) explains this point: "if real GDP is measured by a Laspeyres quantity index, as it is still the case in most countries, an improvement in the terms of trade will actually lead to a fall in real GDP." In contrast, real income focuses on an economy's consumption possibilities, and in turn captures the impact of a change in the relative price of exports to imports. Real income growth attributed to changes in the terms of trade can be significant when there are large fluctuations in import and export prices and the economy under concern is highly exposed to international trade, like a lot of the Asian economies (see Figure 10). In the current global financial storm, volatile exchange rates are observed. To the extent that import and export prices are partially determined by exchange rate movements, the distinction between real GDP and real income may well become more significant in this turbulent period.

The distinction between real income and real GDP lies in the differences between corresponding

deflators. Real GDP is calculated from a GDP deflator aggregating prices of household consumption, government consumption, investment, exports and imports,²⁰ while real income is calculated from the prices of domestic expenditure, consisting of household consumption, government consumption and investment. Therefore real income can be considered as how much domestic expenditure can be purchased with the current income flow.²¹ As such, real income captures the purchasing power of the income flow. Applying the method proposed by Diewert and Morrison (1986), the annual growth rate of *real income* can be fully attributed to two components: *annual growth rate of real GDP*, and real income growth attributed to changes in prices of exports and imports.²² The second component is called the *trading gain* by some authors (Kohli, 2006). This term is adopted in this report.

Figure 17 shows this decomposition of real income for the Asian countries, along with the US and EU15.²³ Trading gain can be positive or negative, depending on the direction of change in the terms of trade. Its impact is modest for many countries, and is less than 2 per cent for most of the time. However, for Hong Kong, Indonesia, Iran, the Philippines, Sri Lanka and Thailand, trading gain is relatively more significant. In 1974, as a consequence of the first oil price shock, the improvement in the terms of trade raised the real income of Iran by 35 per cent – the biggest impact for the entire period across this country group.

Table 7 lists annual average growth rates of real income, real GDP and trading gain for the periods 1970–2006, 1995–2000 and 2000–2006. The general observation is that trading gain effect is small on average over a long period of time, but could be bigger over a shorter period.²⁴ Over the period 1970–2006, although the impact of trading gain is less than 1 per

20 The weight for import price changes is negative. Thus if import prices decrease, this tends to raise the GDP deflator.

21 This definition of real income is the same as Kohli (2004, 2006). An alternative definition is nominal GDP deflated by the price of household consumption; this is adopted by Diewert, Mizobuchi and Nomura (2005) and Diewert and Lawrence (2006).

22 Real income growth can be decomposed into two components as follows:

$$\underbrace{\ln(GDP^t/GDP^{t-1}) - \ln(P_D^t/P_D^{t-1})}_{\text{Real Income Growth}} = \underbrace{\ln(GDP^t/GDP^{t-1}) - (1/2)\sum_{i=1}^n (s_i^t + s_i^{t-1})\ln(P_i^t/P_i^{t-1})}_{\text{Real GDP Growth}} + \underbrace{(1/2)(s_X^t + s_X^{t-1})\{\ln(P_X^t/P_X^{t-1}) - \ln(P_D^t/P_D^{t-1})\} - (1/2)(s_M^t + s_M^{t-1})\{\ln(P_M^t/P_M^{t-1}) - \ln(P_D^t/P_D^{t-1})\}}_{\text{Real Income Growth Attributed to Changes in the Terms of Trade (= Trading Gain)}}$$

where P_i^t is a period t price of good i and s_i^t is a period t expenditure share of good i . D is the domestic expenditure, X is the export and M is the import.

23 There are several studies on the decomposition of real income growth for other countries: Kohli (2004) for 26 OECD countries during 1980–1996, Kohli (2006) for Canada during 1981–2005 and Diewert and Lawrence (2006) for Australia during 1960–2004.

24 Negative and positive effects in shorter periods cancel each other out. In the end, the accumulated effect often becomes negligible.

Unit: Annual growth rate (percentage)

Note: Real GDP is calculated by the implicit Törnqvist quantity index. (The initial observation periods are different for some countries in the table for 1970–2006, due to data availability.)

cent except for Iran, its contribution to real income growth can still be significant for some countries, with real GDP growth underestimating real income growth by 10 per cent and 14 per cent in Malaysia and Indonesia, for example. In Iran, real income growth was 62 per cent higher than its real GDP growth. Conversely, the negative impact from trading gain pulled down real income growth in Nepal, which was only 85 per cent of its real GDP growth.²⁵

The impact of trading gain can have a larger impact over shorter periods. The time period 1995–2000 includes the impact of the Asian financial crisis. For Thailand, the relative trading gain effect more than outweighed the small positive real GDP growth (of 0.02 per cent), giving rise to a marginal fall in real income of 1.02 per cent. In Korea negative trading gain also shaved 44 per cent off real GDP growth of 4.9 per cent, giving a real income growth of 2.7 per cent. Over the more recent period of 2000–2006,

trading gain in Iran and Malaysia was positive, giving rise to real income growth which was 48 per cent and 24.4 per cent higher than real GDP growth respectively. In some countries trading gain effect was unfavorable, resulting in real income growing slower than real GDP – for example by 35 per cent in the ROC, 29 per cent in Korea and Hong Kong and 28 per cent in Japan.

Trading gain has been negative on average in China for all the periods shown in Table 7. Growth in China was the fastest, independent of which measure was used, during the period 1970–2006 and also for 1995–2000. However, for the recent period of 2000–2006, China fell behind Iran and Cambodia in real income growth because of the trading gain effects.

Kohli (2006) further decomposes trading gain into the *terms-of-trade effect* and the *real exchange rate effect*.²⁶ The terms-of-trade effect is the part of real income growth attributed to the change in the relative price

25 According to Kohli's (2004) study on real income of 26 OECD countries during 1980–1996, trading gain on average over the entire period varies across countries, from the smallest effect of

–0.8 per cent (–30.9 per cent of real income growth) per year in Norway to the largest of 0.63 per cent (29.4 per cent of real income growth) per year in Switzerland.

Figure 18: Decomposition of Average Annual Growth of Real Income, 1970–2006

Figure 19: Decomposition of Average Annual Growth of Real Income, 1973–1979

Figure 20: Decomposition of Average Annual Growth of Real Income, 1996–1998

between exports and imports, whereas the real exchange rate effect refers to the part of real income growth attributed to changes in the relative price of traded goods and domestically consumed goods. By applying this result, real income growth can be decomposed into real GDP growth, terms-of-trade effect and real exchange rate effect. Figure 18 applies this decomposition to the Asian countries for the period 1970–2006, and shows that the real exchange rate effect is generally much smaller than the terms-of-trade effect. The sign of the two effects is the same for most countries; Vietnam and Nepal are the exceptions.

Figures 19 and 20 show the decomposition of average annual real income growth, covering two

periods of major economic shocks faced by the Asian economies: during 1973–1978, which includes the two oil price hikes in 1974 and 1978, and 1996–1998 to capture the impact of the Asian financial crisis. High oil prices improved the terms of trade for oil-exporting countries, such as Iran and Indonesia, and worsened the terms of trade for oil-importing countries (Figure 19). Both the terms-of-trade effect and real exchange rate effect were particularly pronounced in Iran. During the Asian financial crisis the real exchange rate effect was large relative to past experience, especially in the Philippines, Indonesia, Malaysia and Korea (Figure 20).²⁷

26 Trading gain can be decomposed into two components as follows:

$$\begin{aligned} & \frac{(1/2)(s_X^t + s_X^{t-1})\{\ln(P_X^t/P_X^{t-1}) - \ln(P_D^t/P_D^{t-1})\} - (1/2)(s_M^t + s_M^{t-1})\{\ln(P_M^t/P_M^{t-1}) - \ln(P_D^t/P_D^{t-1})\}}{(1/4)(s_X^t + s_X^{t-1} + s_M^t + s_M^{t-1})\{\ln(P_X^t/P_X^{t-1}) - \ln(P_M^t/P_M^{t-1})\}} = \\ & \quad \text{Real Income Growth Attributed to Changes in the Terms of Trade (=Trading Gain)} \\ & \quad \text{Terms of Trade Effect} \\ & \quad \frac{(1/2)(s_X^t + s_X^{t-1} - s_M^t - s_M^{t-1})\{(1/2)\ln(P_X^t/P_X^{t-1}) + (1/2)\ln(P_M^t/P_M^{t-1}) - \ln(P_D^t/P_D^{t-1})\}}{(1/2)(s_X^t + s_X^{t-1} - s_M^t - s_M^{t-1})\{(1/2)\ln(P_X^t/P_X^{t-1}) + (1/2)\ln(P_M^t/P_M^{t-1}) - \ln(P_D^t/P_D^{t-1})\}}. \\ & \quad \text{Real Exchange Rate Effect} \end{aligned}$$

27 Kohli (2006) calculated trading gain, the terms-of-trade effect and real exchange rate effect of Canada during 1982–2005. Average annual trading gain over the entire period is very small, at 0.1 per cent. This is small by the standard of Asian economies. However, trading gain became significant, especially for the three years of 2002–2005. Over these years the average trading gain is 1.6 per cent per year. This effect is decomposed into a terms-of-trade effect of 1.4 per cent and real exchange rate effect of –0.1 per cent.

6. Productivity Performance

Labor utilization and labor productivity together determine per capita GDP (Section 3.2). Labor utilization is defined as the number of workers relative to the population (termed the employment rate in this report), to ensure consistency with the definition of labor productivity (i.e. GDP per worker) that is measured in all APO member countries.²⁸ Increasing employment and improving labor productivity could present a policy trade-off in the short term, i.e. they cannot be achieved simultaneously. If the policy target is to increase employment, productivity may suffer in the short term as marginal and less-productive workers are recruited, bringing down the average productivity performance. The huge labor productivity gap between Asia and the US we observe in this chapter should therefore be considered in the context of the generally high employment rate in Asia.

6.1 Labor Utilization

Figure 21 shows cross-country comparisons of employment rates. This is the only indicator on which the average of Asia21 is comparable to the US. China leads the Asian group with an employment rate of 0.58, which was 20.7 per cent and 36.1 per cent higher than the US and EU15 respectively in 2006. Six other economies also had employment rates above that of the US: Cambodia, Thailand, Singapore, Vietnam and marginally Japan and Hong Kong.

Figure 22 charts Asian countries' employment rates relative to that of the US under the same groupings used in Table 5 in Section 3.2. It is clear that Group-C1 countries (Figure 22.1), which have the fastest catch-up speed in per capita GDP against the US, have also had the highest and rising relative employment rates among the Asian countries in the past three decades. The employment rate of China, Thailand and Hong Kong has always stayed above or similar to that of the US. By the end of the period only three out of the nine economies, namely the ROC, Indonesia and Korea, have employment rates below

the US in this group; the remaining countries have overtaken the US. Group-C2 countries (Figure 22.2) have the second-highest relative employment rate as a group, with India and Malaysia hovering around 80 per cent of the US level. While Malaysia's employment rate has been relatively stable, India shows stronger employment growth in the 2000s. Lao PDR is close to the US employment rate, while Sri Lanka started a little lower at around 60 per cent, but is catching up with India and Malaysia in the more recent period.

Countries in Group-C3 have widespread relative employment rates, ranging from 60 per cent to just over 100 per cent of US rates in 2006 (Figure 22.3).

Figure 21: Cross-country Comparisons in Employment Rate, 2006

²⁸ Labor utilization is defined as hours worked per person in the population, as in OECD (2008). Since data on hours worked are available for some selected countries, we use employment rate as labor utilization. In Section 6.2 we

provide labor productivity measures based on hours worked for nine countries. Also, in order to compute total factor productivity in Section 6.3, hours worked data are used for three Asian countries.

Figure 22.1: Group-C1 Countries

Figure 22.3: Group-C3 Countries

Figure 22.4: Group-C4 Countries

Figure 22: Employment Rates Relative to the US, 1970–2006

Three of the countries in Group-C3 have declining employment rates over a long period of time: Japan, Bangladesh and Pakistan. Japan is different from the other two, in that it was in the high-income group and had an employment rate nearly 40 per cent higher than the US at the start of the period. Both Bangladesh and Pakistan were in the lowest-income group and the weakness in employment (declining from 69.9 per cent (Bangladesh) and 78.9 per cent (Pakistan) of the US level in 1970 to around 60 per cent today) accounted for a sizeable share of the per capita GDP gap with the US (at 12.8 per cent and 16.1 per cent respectively – Figure 6). Both Mongolia and Nepal experienced a stronger employment trend in recent years, with Mongolia approaching 100 per cent and Nepal 80 per cent. The employment rate of the EU15 has been relatively stable at just under 90 per cent of the US level.

For Fiji and the Philippines in Group-C4, employment rates contributed only 6.2 per cent and 8.7

per cent to the per capita GDP gap against the US respectively (Figure 6). Figure 22 confirms that most of this negative catch-up rate in per capita GDP is explained by their labor productivity performance and not their employment rates, which were similar to the countries in Group-C2. Iran's employment reached its trough around the 1980s and is only gradually returning to its 1970s' level. In contrast to Fiji and the Philippines, the employment rate explained 34.9 per cent of Iran's per capita GDP gap with the US in 2006.

6.2 Labor Productivity

Labor productivity can be measured in a number of ways. The preferred measure is GDP per actual hour worked, which adjusts for different work patterns across countries and across time.²⁹ However, total actual hours worked can be constructed for only a

²⁹ GDP is valued at basic prices in Sections 6.2 and 6.3, as opposed to GDP at market prices used in the previous chapters.

For details see Box 7.

Figure 23: Labor Productivity Gap against the US by Per-worker GDP and Per-hour GDP

handful of countries studied. To include all countries, therefore, the standard labor productivity measure used in this report is in terms of GDP per worker, which tends to favor countries with longer working hours in the comparisons, other things being equal. To the extent that the high-performing Asian countries tend to work longer hours than the US on average, their labor productivity gaps presented in this report are probably conservative estimates.

Figure 23 shows how the productivity gap against the US varies depending on which measure of labor productivity is used. Total hours worked are constructed for nine countries, although the quality of the estimates may vary across countries. In Figure 23 there is little difference in the productivity gap between the two measures of labor productivity for five out of the nine countries presented, whereas they make a bigger difference for countries with high performance. The labor productivity gap against the US is wider on the GDP-per-hour measure by around 13–14 per cent for the ROC, Hong Kong, Japan and Korea, suggesting that they work longer hours than the US.

Figure 24 shows the cross-country comparisons of labor productivity (defined as GDP per worker from here) in 2006. On this measure, the US set the benchmark for other countries to emulate; but with a gap of 3.1 per cent the performance of the Asian group leader, Singapore, was not significantly different from that of the US. Hong Kong had a wider gap of 12.3 per cent against the US. Japan and the ROC took the third and fourth places among the Asian

Figure 24: Labor Productivity, 2006

group, with a productivity level which was around 30 per cent below that of the US. Korea followed, with a gap of 47.6 per cent. Iran and Malaysia achieved productivity levels of 39.2 per cent and 33.9 per cent of the US level respectively. Thereafter the Asian group displayed a long tail of countries with labor

Unit: US dollars at current basic prices per worker

productivity levels of less than 20 per cent that of the US, pulling down the average performance of the group to 15 per cent for the APO20 and 12.4 per cent for Asia21. Included in the long tail were China and India, with productivity levels that were 9.4 per cent and 6.4 per cent of the US level, respectively.

Table 8 presents cross-country comparisons of labor productivity levels in 1995, 2000, 2005 and 2006. In the past decade Asia as a group achieved little change in its labor productivity relative to that of the US, hovering around 12 per cent for Asia21 and 15–18 per cent for the APO20. Japan was the leader in Asia until 1991, when both Singapore and Hong Kong caught up and overtook it thereafter. In 1995 Singapore, the Asian leader, sustained a productivity gap of 13.6 per cent with the US, but by 2006 the gap was more than halved to 5.8 per cent. Hong Kong's productivity level relative to Singapore has been stable in the past decade, at around 91 per cent.

Comparing the new data for 2006 with 2005 shows that productivity was little changed between the two years, stressing the structural nature of productivity performance, which requires medium- to long-term effort to make statistically significant improvements. In the past decade the top eight countries did not lose their relative positions, although the productivity gap between Japan and the two Asian leaders has been widening while the ROC has been closing up on Japan. China and India, the two giant and fast-emerging economies in Asia, started off with similar labor productivity in 1995; but, one decade later, China is showing signs of pulling ahead of India. China's relative performance moved up from 5.2 per cent to 8.4 per cent of the leader's level between 1995 and 2006, while India managed to move up from 5.9 per cent to 7 per cent over the same period. Not only has China been sustaining the rapid productivity growth in Asia in the past decade, but its growth accelerated to an average of 8.4 per cent a

Unit: Average annual growth rate (percentage)

year in 2000–2006 from 7.1 per cent a year in 1995–2000 (Table 9). This compares with India's 4.5 per cent and 3.1 per cent, and Singapore's 2.5 per cent and 2 per cent, over the same periods. In contrast, average annual productivity growth in the US slowed from 2.4 per cent between 1995 and 2000 to 1.3 per cent between 2000 and 2006, i.e. back to the growth rate of the early 1990s. Among the remaining countries, Indonesia's relative position worsened immediately after the Asian financial crisis; the performance of Nepal and Pakistan has also deteriorated during the periods compared. Looking at the productivity growth rates suggests that Indonesia bounced back strongly after the crisis, from an average of –1.5 per cent a year between 1995 and 2000 to 3.8 per cent between 2000 and 2006, whereas Nepal shifted from a mediocre average annual productivity growth of 0.4 per cent to –0.6 per cent between the two periods.

Figure 25 shows labor productivity level relative to the US (= 100) for the Asian countries. The same grouping as in Section 3.2, based on the speed of catch-up with the US in per capita GDP, is used here. Broadly speaking, countries that are catching up fast with the US in per capita GDP (Group-C1) are also fast in catching up in labor productivity (Figure 25.1). Similarly, countries with deteriorating relative per capita GDP (Group-C4) are also found to be deteriorating against the US in labor productivity (Figure 25.4).

In Figure 25.1 we see three subgroups in Group-C1 countries. The first is made up of Singapore and Hong Kong, which started at relatively high levels and have made most progress in closing the productivity gap with the US. The ROC and Korea make up the second group, and have also made much progress in catching up. However, because they started at a lower level than Singapore and Hong Kong, they

still have a sizeable gap of 30 per cent and 50 per cent, respectively, with the US. The third group is made up of China, Indonesia, Cambodia, Thailand and Vietnam, all of which had productivity levels below 10 per cent of that of the US in 1970 or at the start of the first data series available. China shows signs of a strong and promising start in its catch-up process in the past decade, while the earlier progress made by Thailand and Indonesia appears to have been stalled by the Asian financial crisis of 1997–1998; these countries are slowly recovering the lost ground.

Figure 25.2 shows the performance of Group-C2 countries, which managed an annual catch-up rate of 0.5 per cent to under 2 per cent in per capita GDP against that of the US. Malaysia has the highest relative income as well as labor productivity in this group. During the period 1982–2006 its relative labor productivity improved from 23.7 per cent to 35.7 per cent against that of the US. Like Thailand and Indo-

nesia, Malaysia's catch-up effort was frustrated by the Asian financial crisis of the late 1990s, but its relative productivity level is approaching its previous peak of 35.6 per cent achieved in 1997. The relative productivity performance of the remaining three countries in this group, namely Sri Lanka, India and Lao PDR, has been little changed.

Countries which have managed little catch-up with the US in per capita GDP (Group-C3) are also those with rather stagnant labor productivity. Japan is the only high-income country in this group, while the rest are all low-income countries with per capita GDP less than 10 per cent of that of the US. Japan showed strong catch-up in the earlier period, with relative labor productivity peaking at 75 per cent of that of the US in 1991, and since 2000 the subsequent decline has been halted. Similarly the EU15, a reference economy with high income, also has its productivity gap widening against the US since the early 1990s. The low-income countries have man-

Figure 25: Labor Productivity Level, 1970–2006: Relative to the US

Box 7: Adjustments for the Construction of GDP at Basic Prices

GDP can be valued using different price concepts: market prices, factor cost and basic prices. If the price concept is not standardized across countries, it will interfere with the international comparisons. All the countries that we cover in this *Databook* officially report GDP at market prices, but this is not true for GDP at factor cost and GDP at basic prices. Thus international comparisons in Section 3 (on economic scale and growth) and Section 4 (on final demand) are based on GDP at market prices. However, by valuing output and input at the prices that producers actually pay and receive, GDP at basic prices is a more appropriate measure of countries' output than GDP at market prices for international comparisons of total factor productivity and industry performance, as it is a measure from the producer's perspective. Hence, Sections 6.2 and 6.3 on whole-economy productivity performance are based on GDP at basic prices. Our results, shown in Figure B7, suggest that the impact of different price concepts on productivity comparisons is far from trivial. However, due to the constraints of the official data, we could not standardize the price concept for industry GDP, which therefore varies across countries. In Chapter 7 on industry performance, industry GDP at basic prices is used for Korea, Iran and Nepal, and industry GDP at factor cost for Fiji, India, Lao PDR and Pakistan, while industry GDP at market prices is used for the remaining countries. Readers should bear in mind that the use of various price concepts clouds the cross-country comparisons of industry performance, but we are unable at this stage to specify to what extent.

The 1993 SNA defines GDP at market prices "from the expenditure side as total final expenditures at purchasers' prices less total imports valued free on board (f.o.b.) (and not at purchasers' prices including taxes less subsidies on imports). Thus, although imports valued f.o.b. are valued in the same way as exports, they are not valued consistently with other final expenditures nor with the entries in the production account, so that the identity between GDP from the expenditure side and GDP from the production side breaks down. As import taxes are not deducted along with total imports f.o.b. when calculating GDP from the expenditure side, it follows that import taxes must be added to GDP from the production side in order to restore the identity. Thus, GDP at market prices as defined in the System is the sum of the gross values added of all resident producers at market prices plus taxes less subsidies on imports" (para. 6.235). The 1993 SNA defines GDP at basic prices as "output valued at basic prices less intermediate consumption valued

at purchasers' prices. Although the outputs and inputs are valued using different sets of prices, for brevity the value added is described by the prices used to value the outputs. From the point of view of the producer, purchasers' prices for inputs and basic prices for outputs represent the prices actually paid and received. Their use leads to a measure of gross value added which is particularly relevant for the producer" (para. 6.226). GDP at factor cost, on the other hand, excludes all indirect taxes on production and includes all subsidies. It is, however, not a concept explicitly used in the 1993 SNA.

As the 1993 SNA explains, these three concepts of GDP differ in the treatment of indirect tax and subsidies. Indirect tax consists of "taxes on products," which are payable on goods and services mainly when they are produced, sold and imported, and "other taxes on production," which are all indirect taxes except "taxes on products" that enterprises incur as a result of engaging in production. VAT and import duties are part of "taxes on products," and "other taxes on production" consists mainly of taxes on the ownership or use of land, buildings or other assets used in production, or on the labor employed and compensation of employees paid. Subsidies consist of "subsidies on products," which are payable on goods and services mainly when they are produced, sold and imported, and "other subsidies on production," which are subsidies except on "subsidies on products" that producers receive as a consequence of engaging in production. Import and export subsidies are example of "subsidies on products" and subsidies on payroll or workforce and subsidies to reduce pollution are examples of "other subsidies on production."

Since GDP at basic prices is available for only a few countries, such as Iran and Korea, we need to construct at basic prices, we subtract "taxes on products" from and add "subsidies on products" to GDP at market prices, which is available for all the countries studied. The main data sources for estimating "taxes on products" and "subsidies on products" are tax data in national accounts and the IMF's Government Finance Statistics (GFS). Many countries report "indirect taxes" ("tax on products" plus "other taxes on production") and "subsidies" in their national accounts. We estimate "taxes on products" by using the sum of "taxes on goods and services" and "import duties" taken from GFS, which we assume to be a good approximation for "taxes on products." "Other taxes on production" are then obtained by subtracting "taxes on products" from "indirect taxes." While we are able to split the "indirect taxes" into "taxes

(continued on next page)

(continued from previous page)

on products" and "other taxes on production," not enough information is available to do the same for "subsidies." We assume that ("subsidies on products"/"other subsidies on production") is the same as ("tax on products"/"other taxes on production"). In other words, we obtain "subsidies on products" by applying to "subsidies" in total the ratio of "taxes on products" to "indirect taxes," and "other subsidies on production" are estimated as a residual. In some countries, only "net indirect taxes" ("indirect tax" minus "subsidies") is available. In this case, we calculate "indirect taxes" by adding "subsidies" which is taken from GFS to "net indirect tax." After that, we follow the exactly same steps as explained above. For countries where only tax data from GFS are available, we simply regard "subsidies" taken

from GFS as "subsidies on products" as an approximation.

Figure B7 shows the difference between GDP at market prices and GDP at basic prices expressed as a proportion of GDP at market prices. Our results show that not only is the difference between the two concepts non-trivial, but the size of divergence also varies across countries, from -0.12 per cent in Iran to 14.1 per cent in Mongolia. Given that the basic price is the price which a producer actually faces, it is the proper concept to value output for productivity comparisons. Our estimated gaps between GDP at market prices and GDP at basic prices, and their variation across countries, make the results of productivity comparisons based on GDP at market prices somewhat suspicious.

Figure B7: Difference between GDP at Market Prices and GDP at Basic Prices, 2006

aged little catch-up; if anything there was a small drop in their relative productivity at the beginning of this millennium, although they have stabilized since then (Figure 25.3).

Figure 25.4 shows that countries with declining per capita GDP against that of the US (Group-C4), namely Iran, the Philippines and Fiji, also have declining relative labor productivity. Among them, Iran experienced the most drastic decline. Its relative labor productivity declined from its former peak of 78.3 per cent three decades ago to 42 per cent in 2006. Fiji's decline was from a peak of 18.3 per cent in the late 1970s to 10 per cent in 2006, whereas the corresponding figures for the Philippines were 11 per cent achieved in the late 1970s to 8.6 per cent in 2006.

6.3 Total Factor Productivity

Labor productivity in Section 6.2 is only a one-factor or partial-factor productivity measure and does not provide a full perspective of production efficiency. An observation of low labor productivity could suggest production inefficiency, but it could also be a mere reflection of different factor input intensities in the chosen production method optimal to the given set of factor prices faced by the economy concerned. By observing relative movements in labor productivity alone, it is not easy to distinguish which is the case. In populous Asian economies, which are relatively abundant in low-skilled labor, production lines may be deliberately organized in a way that utilizes this

abundant, and hence relatively cheap, resource. It follows that the chosen production method is most likely to be (low-skilled) labor intensive with little capital, manifested in low labor productivity. This is why economists analyze total factor productivity (TFP), which is GDP per unit of combined inputs, to get a more complete picture of countries' production efficiency.³⁰

In this section we report a first set of results of the APO Productivity Database on capital services and TFP estimates for the ROC, Japan, Korea and China for which the long-time investment data at current prices are available or estimated. The economic growth is decomposed into its sources from factor inputs and total factor productivity based on the methodology developed by Jorgenson and Griliches (1967). This report defines output as GDP at basic prices, and factor inputs as labor, IT capital and non-IT capital.³¹ Labor input is measured by total hours worked (except for China), without adjustments for changes in labor quality.³²

Capital input is a key factor for measuring productivity, and is defined as capital service – the flow of services from productive capital stock. The 1993 SNA recommends constructing the national balance-sheet account for current official national accounts, but this is still not a common practice in the national accounts of many Asian countries.³³ Even if the estimates of net capital stocks are available for the whole economy, the assumptions and methodology can differ considerably among countries. As a result, the harmonized estimates for productive capital stocks and services have been developed in the APO Productivity Database.³⁴ In our methodology the change in the quality of capital is incorporated into the measurement of capital services in two ways: change in the composition is captured by explicitly differentiating assets into 10 types (Box 9); and by using an appropriate and harmonized deflator for IT capital to reflect its rapid quality change embodied in IT-related assets (Box 10).

Figure 26 presents the sources of economic growth for the selected countries during 1970–2006. Cross-country comparisons of the long-term decomposition of economic growth are shown in Figure 26, for the period 1970–2006. For the whole period of our estimation, Japan and Korea have similar averages of annual growth rates of TFP, ranging from 0.5 per cent to 0.6 per cent. However, the sources of economic growth in these countries are considerably different. In Japan the main engine was an expansion of capital input, contributing about 82 per cent (13 per cent by IT capital and 69 per cent by non-IT capital) of the economic growth during 1970–2006. The average annual TFP contribution was 20 per cent. In Korea, TFP has achieved a smaller role in economic growth, accounting for 8 per cent of economic growth in the long run, whereas growth of capital services (largely from non-IT capital) contributed 75 per cent.

TFP growth in the ROC is superior to Korea's experience. The average annual TFP growth and TFP's contribution to economic growth are 1.6 per cent (compared to 0.5 per cent in Korea) and 23 per cent (compared to 8 per cent) respectively during 1970–2006. Our findings of discrepant TFP contributions in these two countries are consistent with the estimates in some preceding studies. For example, Young (1995) shows that TFP contributions to the non-agriculture economy's growth were 17 per cent in Korea and 28 per cent in the ROC during 1966–1990. The findings in Timmer and van Ark (2000) were 6 per cent in Korea and 13 per cent in the ROC for the period 1963–1996, based on their own estimates of capital services.

China's productivity performance has been outstanding in this period. The average TFP growth was 3.1 per cent per year during 1970–2006. This compares to the long-run estimates of 3.8 per cent during 1978–2005 in Holz (2006) and also 3.8 per cent during 1978–2004 in Bosworth and Collins (2007). The Chinese experience of long-term TFP growth

30 When there is only one input and one output, TFP is defined as the ratio of the rate of output to input. The proportion of output growth which is not attributed to input growth can be considered as an improvement in production efficiency. When there are several types of inputs and outputs, both are aggregated by using index number and TFP is calculated as the output quantity index divided by the input quantity index. In this chapter, the Törnqvist quantity index is used for aggregating labor and capital.

31 IT capital is defined as a composite asset of IT hardware (computers and copying machines), communications equipment and computer software.

32 The failure to take into account improvements in labor quality leads to TFP overestimation (see Box 8). The mea-

surement of labor quality covering Asian countries is the next challenge for APO Productivity Database project.

33 Only half the APO member countries estimate balance-sheet accounts for the national economy (Nomura, Lau and Mizobuchi, 2008).

34 This report basically follows the methodology used in the OECD Productivity Database (Schreyer, Bignon and Dupont, 2003). The main difference is that we incorporate the capital input by residential buildings, although this is omitted in the OECD Productivity Database. The new OECD (2009) manual *Measuring Capital*, prepared by Paul Schreyer, provides a comprehensive framework for constructing prices and quantities of capital services.

Box 8: Measuring Labor Quality

If worker skills are improving but not appropriately reflected in the volume index of labor input, then total factor productivity growth estimates will be overstated. Labor quality is affected by investment in human capital, such as education, work experience and training offered. These factors change over time and with a country's development experience, and in turn have a direct impact on labor supply. In theory a worker with higher education or more work experience works more efficiently, so improved worker skills should be reflected in the volume of labor supply expanding faster than the simple head or hours-worked count.

To take into account of this workforce heterogeneity, the workforce is first distinguished into different worker types, which is then weighed by their marginal productivity, approximated by their respective shares of the total compensation under the conditions of competitive markets and constant returns to scale. Let L be the volume of labor input, which is differentiated into n types, h_i to h_n : $L = g(h_1, h_2, \dots, h_n)$. The growth rate of these heterogeneous total hours worked is then aggregated according to the following equation as a

Törnqvist index: $\ln \left[\frac{L(t)}{L(t-1)} \right] = \sum_i \left[\frac{w_i(t) + w_i(t-1)}{2} \right] \ln \left[\frac{h_i(t)}{h_i(t-1)} \right]$, where $w_i(t)$

is the nominal share of labor compensation for i type of labor. The weight is therefore the average of $w_i(t)$ and $w_i(t-1)$, and the weights sum to one.

For example, in the UK total hours worked are differentiated into 576 types according to workers' attributes defined by eight qualification levels, six age groups, six industries and two genders. The primary source of these data and the corresponding wage share of each worker type is the Labour Force Survey, with data being adjusted to be consistent with the national accounts (see ONS, 2007). Compiling a volume index of quality-adjusted labor input measures can be a data-intensive exercise. While many countries with a less mature statistical system will not be able to support such data demand, improvement in labor quality, primarily through education, could be a key element that sets coun-

tries apart in their development. It is therefore unsatisfactory not to track explicitly the impact of worker skills in the less advanced countries, even if it means that the methodology will need to be much simplified.

From our survey of national accounts in Asia (see Box 2 and Nomura, Lau and Mizobuchi, 2008), we have learnt that continuous employment data and total actual hours worked are not available for some APO member countries, let alone data on worker characteristics. But socio-economic data from the population census can be used as an alternative data source. Our survey shows that all participating countries have a population census. For some countries it is a decennial exercise, while for others it is quinquennial.

A simpler approach may focus on adjusting labor input volume for education only. International datasets of educational attainment have been developed for a broad group of countries, using a combination of data sources to infer the proportion of the adult population in each country that has attained a certain level of education for each year. By assuming that the education profile of the population was representative of the educational profile of the workforce, Collins and Bosworth (1996) used the dataset and the extrapolation procedures developed by Barro and Lee (1994) (later updated in Barro and Lee, 2001) to adjust the labor input measure for their TFP calculations in their analysis of economic growth in East Asia. For the weights, Collins and Bosworth (1996) used the observed relative earnings of different educational groups, reflecting the assumption that percentage returns to schooling were constant across levels of schooling and countries. Although the estimation method is far from perfect and may suffer from potentially serious measurement problems, it is still a worthwhile step forward toward utilizing the existing, albeit sparse, information that may infer changes in labor quality in some of the less advanced countries. Sensitivity analysis can always be employed to check the robustness of assumptions, and in turn the results.

of over 3 per cent is not unprecedented in Asia. According to Jorgenson and Nomura (2005), Japan also achieved an annual TFP growth of 3.1 per cent during 1960–1973, even after improvements in labor quality have been taken into account in the estimation of labor growth (and, as such, eliminating over-estimation in TFP).³⁵

There has been a longstanding debate on what drives growth in Asia (Box 6). Looking into the shorter time periods, the evolution of the decompo-

sition of economic growth over time can be traced (Figure 26) and may offer some insights into the debate between accumulation and assimilation. According to our findings, it is true that, historically, capital accumulation has played a much more significant role in the Asian countries than in the US. But the relative contribution shares are not constant over time; there were periods when TFP growth increased its weight in driving growth. In particular, there has been a resurgence in TFP growth in recent years

35 In the same period of 1960–1973 the average annual contribution rate of labor quality improvement to growth is measured as 0.54 per cent in Jorgenson and Nomura (2005).

Figure 26: Sources of Economic Growth, 1970–2006

(2000–2006) in Japan and Korea after the Asian financial crisis, raising its contribution to economic growth to a significant level.

In the ROC the main growth engine was capital growth (accounting for 66 per cent of economic growth) followed by labor growth (20 per cent) in 1970–1985. During 1985–1995 the contribution of TFP growth strengthened to 41 per cent of economic growth, up from 14 per cent in the previous period. In the most recent decade, however, capital has been the main engine of growth once again: the contribution from IT capital more than tripled when compared with the previous periods. In Japan capital was the main engine of growth until 2000. In the first half of the 2000s there has been a surge in TFP

growth, reaching 1.13 per cent on average a year in 2000–2006, up from 0.34 per cent in 1995–2000. TFP growth alone accounted for 76 per cent of economic growth in the latter period. In contrast, the contribution from labor input has been declining since 1995.

In Korea capital accumulation was key during the period 1970–1985, accounting for 95 per cent of economic growth, while TFP growth made a negative contribution.³⁶ However, Korea experienced two periods of strong TFP growth thereafter, at 2.47 per cent on average a year in 1985–1995 and 1.84 per cent in 2000–2006. The respective contribution shares were 52 per cent for capital and 41 per cent for TFP in the latter period. Also note that the

36 Note that our TFP estimates in the 1970s for Korea may require further investigation. Based on Young (1995), the Korean TFP growth in the same periods shows positive contributions: the average annual growth rates are 1.9 per

cent, 0.2 per cent and 2.4 per cent for 1970–1975, 1975–1980 and 1980–1985. On the other hand, Timmer and van Ark (2000) measure the negative TFP growth as -0.35 per cent during 1970–1985.

Figure 27: IT Capital Contribution to Total Capital Input

contribution from IT capital has also doubled in the past decade.

In China TFP growth has been strong throughout the period of our estimation. The fastest TFP growth of 4.18 per cent was achieved during the period 1985–1995, accounting for 44 per cent of economic growth. In the past decade the effort of capital accumulation has strengthened. TFP growth has slowed to 2.7–2.9 per cent compared to the previous decade, with its contribution share dropped to 31–33 per cent. The role played by IT capital has also been strengthened over the years, albeit from a very low base.

Figure 27 presents the contribution of IT capital to total capital input for the economy as a whole. Jorgenson and Nomura (2005) indicated the rapid changes of capital allocation in Japan. In the 1980s IT capital contributed 31.9 per cent of the growth of total capital inputs in the US, as measured in Jorgenson, Ho and Stiroh (2005), but only 13.5 per cent in Japan.³⁷ Since 1995 the Japanese economy has rapidly shifted its capital allocation from non-IT capital to IT capital. In 2000 the contribution of IT capital rose to 42.5 per cent, approaching the 46 per cent in the US. A similar allocation shift to IT capital is also found in the ROC and Korea, although the timing is somewhat later due to the impacts of the Asian financial crisis. After the dot.com crash the contribution of IT capital went back to the level before 1995

in the US, ROC and Korea. Investment in IT capital is a necessary step to adopting and benefiting from the advancements in information and communication technology. Unlike technological advancements in the past, which were largely confined to manufacturing, ICT is a technology that can permeate the sand and bring about significant production gains in, for example, wholesale and retail, banking and finance, and transportation and telecommunications. Given the weight of the service sector in the economy (see Figure 30 for the Asian countries), its potential and implications for economic development and productivity gains could therefore be immense.

Within the same growth accounting framework, average labor productivity (ALP) growth at the aggregate level can be decomposed into effects of capital deepening (capital input per hour worked), which reflects the capital-labor substitution, and TFP. In other words, these factors are key in fostering labor productivity. The decomposition of labor productivity growth is presented in Figure 28. Over the long term (i.e. 1970–2006), labor productivity growth is predominantly explained by capital deepening in Japan (80 per cent) and Korea (88 per cent). In the ROC capital deepening explains 68 per cent and TFP 32 per cent of labor productivity growth. In China, however, the split between the two sources is roughly half-half. Over the shorter periods of time it is possible to see that the role played by TFP has

37 Based on our own estimates presented, IT capital contributes 38.5 per cent in the US and 18.5 per cent in Japan. Although the estimates in the 1980s in this report are somewhat higher than the industry-level estimates in Jorgenson, Ho

and Stiroh (2005) and Jorgenson and Nomura (2005), the trends of both countries shown in Figure 27 are very similar to Figure 3 in Jorgenson and Nomura (ibid.).

Figure 28: Decomposition of Labor Productivity Growth, 1970–2006

weakened in the ROC, with a contribution of 16 per cent in 2000–2006 dropping from its height of 54 per cent in 1985–1995. In contrast, TFP growth has strengthened in Japan, accounting for 54 per cent of labor productivity growth in 2000–2006, up from 17 per cent in 1995–2000 and 24 per cent in 1985–1995. Korea also saw a lift of TFP growth in recent years, and its contribution to labor productivity

growth (at 47 per cent) move back to a similar share as before the Asian financial crisis. In China we see the shrinking role of TFP growth as the role of capital accumulation rises in explaining labor productivity growth. Even so, in recent years TFP growth still explains around one-third of labor productivity growth.

Box 9: Measuring Capital Services

The authors estimated capital services and TFP for five countries, namely the ROC, Japan, Korea, China and the US. The long-term investment data are available or estimated since 1951 for the ROC, 1955 for Japan, 1970 for Korea, 1952 for China and 1901 for the US. The current-price investment data by 10 types of assets (shown in Table B9) are estimated based on the official national accounts, GFCF in benchmark input-output tables and domestic supply data of fixed assets. On the estimation of constant-price investment data, see Box 10.

On measuring capital stock, we basically follow the current framework of the OECD Productivity Database in Schreyer, Bignon and Dupont (2003). The OECD assumes the truncated normal distribution as profiles for asset discarding (retirement), and the hyperbolic distribution as profiles for asset decaying. The age-efficiency profile (AEP) is defined as a combined distribution of discard and decay of assets. The AEP in each asset is based on the two parameters in hyperbolic function: T (average service life) and β ($-\infty < \beta \leq 1$). The hyperbolic function becomes one-hoss shay (no decay until T) when $\beta=1$ and linear when $\beta=0$. We set these two parameters as shown in Table B9.

To estimate the capital services for the whole economy, the user costs of capital by type of asset should be estimated for aggregating different types of capital. The user cost of capital of a new asset (with type of asset denoted as k as of the period of t) $u_{t,0}^k$ is defined as $q_{t-1,0}^k \{r_t + (1 + \zeta_t^k) \delta_{p,t,0}^k - \zeta_t^k\}$, where r_t , $\delta_{p,t,0}^k$, and $q_{t,0}^k$ are the expected nominal rate of return, cross-section depreciation rate and asset price, respectively. The asset-specific inflation rate ζ_t^k is defined as $(q_{t,0}^k / q_{t-1,0}^k - 1)$. The OECD

assumes the country-specific *ex ante* real rate of return r^* , that is constant for the whole period, and defines the nominal rate of return as $r_t = (1 + r^*)(1 + p_t) - 1$, where p_t represents the expected overall inflation rate, defined by a five-year centered moving average of the rate of change of the consumer price index.

One of the main difficulties in applying the *ex ante* approach for measuring user cost of capital is to obtain proper estimates for real rates of return, which can considerably differ among countries and over time. On the other hand, the *ex post* approach originated from Jorgenson and Griliches (1967) enables us to estimate it based on observed data. Assuming constant returns to scale and competitive markets, capital compensation can be derived from the summation of the capital service cost V_t^k for each asset, which is defined as the product of the user cost of capital and the productive capital stock, i.e. $V_t = \sum_k V_t^k = \sum_k u_{t,0}^k S_t^k$. Based on this identity and the n -equations of user cost of capital, the $n+1$ variables of $u_{t,0}^k$ and r_t are simultaneously determined, using the observed capital compensation V_t as the total sum of V_t^k that is not observable in each asset. Note that the depreciation rate $\delta_{p,t,0}^k$ is not independent of the estimated r_t .

The estimated results of *ex post* real rate of return based on $r_t^* = (1 + r_t) / (1 + p_t) - 1$ for five countries are shown in Figure B9. The real rate of return ranges from 6 per cent (Japan) to 17 per cent (ROC) in 2006. Using these *ex post* estimates, the aggregate capital services are measured in this report. The difference caused by the *ex ante* and *ex post* approaches may provide a modest difference in the growth measure of capital services, regardless of the substantial differences in the rates of return and capital compensations (Nomura, 2004).

Table B9: Parameters in Hyperbolic Function

	T	β
1. IT hardware	7	0.50
2. Communications equipment	15	0.50
3. Transportation equipment	15	0.50

Box 10: Price Harmonization on IT Capital

For cross-country comparisons, it has been noted that there is a large diversity in the treatment of quality adjustment in price statistics among countries. It is well known that prices of constant-quality IT capital have been falling rapidly. Cross-country comparisons will be significantly biased if some countries adjust their deflators for quality change while others do not. Price harmonization is sometimes used in an attempt to control for methodological differences in the compilation of price indices, under the assumption that individual countries' price data fail to capture quality improvements. Assuming that the relative price of IT to non-IT capital in the countries compared is set equal to the IT to non-IT price relative in the reference country, the harmonized price is formulated as: $\Delta \ln \hat{p}_{IT}^X = \Delta \ln p_{IT}^X + (\Delta \ln p^{ref} - \Delta \ln p_{nIT}^{ref})$, where the superscript X denotes the country included in the comparisons, p_{IT} is the price of IT capital and p_{nIT} is the price non-IT capital. The price of IT capital in country X , $\hat{p}_{nIT}^X$, is computed by the observed prices p_{IT}^{ref} and p_{nIT}^{ref} in the reference country and p_{nIT}^X in X . Schreyer (2002) and Schreyer, Bignon and Dupont (2003) applied price harmonization to OECD capital services, with the US as a reference country, since the possible error due to using a harmonized price index would be smaller than the bias arising from comparing capital services based on national deflators.

Nomura and Samuels (2004) examined IT prices in the US and Japan at the US SIC (standard industry classification) three-, four- and five-digit levels, adjusting the difference in concept and coverage. In the Corporate Goods Price Index (CGPI) in Japan, Bank of Japan (BOJ) started to use the

hedonic approach from its 1990 benchmark revision for personal computers, mainframes and magnetic disk devices, regressing the hedonic function on an annual basis. Comparing the US and Japan data for PCs and general-purpose computers and servers at the five-digit level from 1995 to 2003, there is a small gap between these two countries resulting from the difference in the definition of index numbers for aggregation of the most detailed items. At the four-digit level, after adjustment of the index numbers and the aggregation weights for the CGPI to be consistent with the BEA's (Bureau of Economic Analysis) output price, the resulting price declines for electronic computers are comparable, with prices falling by 29.3 per cent per year in the US compared to 27.0 per cent in Japan during 1995–2003. Moving to the three-digit level, the aggregate price of electronic computers and peripheral equipment shows that prices fell by 23.8 per cent per year in the US compared to 15.5 per cent in Japan. At the three-digit level, a significant portion of the remaining price gap can be explained by the peripheral equipment price, which fell less rapidly in Japan and has a bigger share of total output when exports are included.

Figure B10 compares the domestic output prices of electric computers in the BLS's (Bureau of Labor Statistics) Producer Price Index (PPI) and BOJ's CGPI during 1993–2005. Over this period, average annual rates of decline were 23.0 per cent in the US and 23.9 per cent in Japan. There may be no considerable gap to be adjusted by the use of a US harmonized price index for electric computers.

Figure B10: Comparison of Producer Prices for Electric Computers between the US and Japan

7. Industry Performance

7.1 Industry Structure and Economic Development

This chapter provides the industry origins of economic growth and labor productivity growth in Asian countries. Industry structure is a key indicator of an economy's stage of development. At one end of the spectrum are predominantly agricultural and rural-based economies, whereas at the other end the agricultural sector is negligible and the service sector is the dominant economic base. In the middle is a stage where manufacturing is the main driver of the economy. By analyzing the industry structure of Asian economies, we can clearly trace the path of economic development and identify country groupings based on similar characteristics.

Table 5 in Section 3.2 introduces a country grouping according to stages of development (as measured by per capita PPP-GDP relative to the US). Table 10 regroups countries based on the same set of criteria as in Table 5, but applied to countries' 2006 income levels. The difference in countries' relative per capita GDP between the two tables reflects the impact of their catch-up efforts since 1970 or the beginning year of the data series in this report for the country concerned.

During this period we saw countries with fast catch-up moving up in income group as they narrow the gap with the US. Among Group-C1 countries, Hong Kong and Singapore move from Group-L2, and the ROC from Group-L3, to Group-L1 to join

Japan; Korea moves from Group-L3 to Group-L2; and Indonesia, Vietnam and China move from Group-L4 to Group-L3. Cambodia and Thailand are the only two countries which fail to move up in income group despite their fast past of catch-up. This, however, masks the noticeable progress Thailand has made during this period, with its relative income rising from 6.6 per cent to 17.7 per cent of that of the US (within the income range of Group-L3). The reason behind Cambodia's failure to move up in income group is its short time series, which starts in 1993. Therefore, despite its average catch-up speed of 3.8 per cent per annum, it has had less time to catch up than other countries with series starting from 1970. Between 1993 and 2006 Cambodia's relative income moved up from 2.3 per cent to 3.8 per cent of the US level.

All Group-C2 countries, except Lao PDR, have managed to move up one level in the income grouping: Malaysia from Group-L3 to Group-L2, and India and Sri Lanka from Group-L4 to Group-L3. Lao PDR's relative income has also improved from 3.4 per cent to 4.6 per cent, even though its time series starts more than a decade later than most countries, in 1984. There are no significant movements of countries in Group-C3 and Group-C4. Pakistan is the only country which moves up in income group from Group-L4 to Group-L3, but its improvement was only marginal over the past three decades, from 5.0 per cent to 5.5 per cent.

Figure 29 shows the industry composition of the Asian economies in 2006, and ranks countries by the

Table 10: Country Groups Based on the Current Economic Level and the Pace of Catching Up with the US

GDP Level to the US	Annual Rate to Catch Up to the US			
	(C1) 2% <	(C2) 0.5% < - < 2%	(C3) -0.5% < - < 0.5%	(C4) < -0.5%
(L1) 60% <	ROC, Hong Kong, Singapore		Japan, EU15	
(L2) 20% < - < 60%	Korea	Malaysia		Iran
(L3) 5% < - < 20%	Indonesia, Thailand, Vietnam, China	India, Sri Lanka	Mongolia, Pakistan	Fiji, Philippines
(L4) < 5%	Cambodia	Lao PDR	Bangladesh, Nepal	

The annual catch-up rates are estimated based on the data during 1970–2006. (The initial observation periods are different for some countries due to data availability.)

The GDP level is defined as a ratio of per capita PPP-GDP between each country and the US in 2006.

Figure 29: Industry Composition of Total Value Added, 2006

share of their agricultural sector in total value added.³⁸ Industries are classified into four groups: agriculture, manufacturing, services and other industries.³⁹ Figure 29 indicates a broad negative correlation between the size of the agricultural sector and the relative per capita GDP against the US. In other words, the more an economy relies on its agricultural sector, the poorer the country is. In Figure 29 it is observed that the six poorest countries top the ranking by the size of the agricultural sector (i.e. Group-L4 countries plus Pakistan and Vietnam, both of which have marginally moved up to Group-L3 with a relative income of 5.4 per cent and 5.5 per cent that of the US respectively). They are followed by Group-L3, and then Group-L2. Group-L1 economies, in line with the US as the reference country, have the smallest agricultural sectors among the Asian countries.

Figure 30 shows the industry shares of value added and employment by four country groups and the US.⁴⁰ The first thing to note is that the service sector accounts for the largest share of the economy in all country groups, independent of their economic de-

velopment. Secondly, each stage of economic development is associated with a distinctive industry structure. Group-L4, the poorest countries, have the largest agricultural sector, whereas the richest countries (Group-L1) have the largest service sector. In between are economies in transition, with a rapidly shrinking agricultural sector and a relatively prominent manufacturing sector. If Figure 29 is ranked by the size of service sector, Hong Kong will top the table at 90.1 per cent, followed by the US (76.7 per cent) and other Group-L1 countries, namely the ROC (69.5 per cent), Japan (68.8 per cent) and Singapore (68.6 per cent). Fiji is an exception, with a large service sector share (66.2 per cent) relative to its per capita GDP level.

Thirdly, Asian countries differ from the US industry structure in the relative importance of manufacturing, even in Group-L1 countries, where manufacturing accounts for 20.4 per cent of the economies' value added, compared with 13.4 per cent in the US. The US economy is highly skewed towards the service sector, accounting for 76.7 per

38 Unlike in the previous chapters, GDP is not necessarily valued at basic prices in this chapter. See Box 7.

39 The agriculture sector is composed of agriculture, forestry, fishing and hunting. The service sector is composed of all the service industries, such as wholesale, retail, transportation, information, finance, education, healthcare,

entertainment, accommodation, restaurants and government. The other industries sector is composed of mining, utilities and construction.

40 The group averages as industry share of value added are based on their GDP using market exchange rates.

Figure 30: Industry Share of Value Added and Employment by Country Group, 2006

cent of the total value added, compared with an average of 69.5 per cent in the Group-L1 countries. This suggests that Asian economies could experience further deindustrialization and a shift in prominence towards services as they continue to mature. The relative prominence of manufacturing in the Asian regional economy as a whole is reflected in the fact that income groups are not filtered out by the size of a country's manufacturing sector. If Figure 29 ranks the size of the manufacturing sector, China (a Group-L3 country) leads with a share of 43.3 per cent. It is followed by Thailand, also a Group-L3 country, at 34.8 per cent, and Malaysia and Korea (Group-L2 countries) at 29.0 per cent and 28.0 per cent respectively. Singapore (a Group-L1 country) at 26.2 per cent and Indonesia (a Group-L3 country) at 27.3 per cent also have manufacturing sectors similar in size to Thailand and these Group-L2 countries.

Figure 31 shows how the share of the agricultural sector in total value added shrank over time in the Asian economies. This could reflect the actual decline in agricultural output and/or the relatively rapid expansion in other sectors. Despite the wide spread, the downward trend is unmistakable, even for Group-L4 countries. With the exception of Iran, the share of the agricultural sector displays a long-term declining trend in all countries, albeit at different paces. Looking at the available data, the share of agriculture in most Asian countries clustered around the 30–40 per cent band in the 1970s, trending down to the 10–20 per cent band by 2006. Vietnam and Mongolia are

two countries where the agricultural sector experienced similar relative decline but within a much shorter time span (from the late 1980s and the mid-1990s respectively). The relative decline of the agricultural sector was most rapid in Korea, from 29.2 per cent of total value added in 1970 to 3.3 per cent in 2006. In many countries the share of the agricultural sector was more than halved between 1970 and 2006: for example, from 42.1 per cent to 12.9 per cent in Indonesia, from 42.3 per cent to 17.8 per cent in India and from 39.6 per cent to 19.4 per cent in Bangladesh. In China the share of the agricultural sector also significantly declined, from 35.4 per cent in 1970 to 11.7 per cent in 2006.

Despite the relative decline of agriculture's share in total value added, employment in the sector for Asia as a whole still accounted for 43.6 per cent of total employment in 2006. Figure 32 shows countries' industry shares in total employment, and ranks countries by the size of employment in the agricultural sector. The five countries⁴¹ which top Figure 29 also top Figure 32, with the exception of China and India. Figure 30 also gives the industry structure (in terms of employment) by country group. The agricultural sector is the only industry sector among all the country groups that has a disproportionately higher employment share than justified by its share in value added. This suggests that agriculture is still highly labor intensive and/or there is a high level of underemployment in the sector in Asia, both of which imply that the labor productivity level is low

⁴¹ Data for Lao PDR are unavailable for Figure 32.

Figure 31: Trends of Value Added Share in the Agriculture Sector, 1970–2006

Figure 32: Industry Share of Total Employment, 2006

Figure 33: Trends of Employment Share in the Agricultural Sector, 1975–2006

compared to other industry sectors.⁴²

The trend of employment share over time (Figure 33) suggests that the relative decline in the share of agriculture in total value added has been accompanied by a downward trend in its share in total employment. This downward trend is unmistakable in most countries plotted in Figure 33. However, the decline in share does not always reflect an actual fall in employment for the agricultural sector. Rather, it could reflect total employment rising faster than employment in agriculture. Among the Asian countries in Figure 33, only the ROC, Japan and Korea have been experiencing a consistent fall in actual employment in the agricultural sector, whereas for Bangladesh, Iran, Cambodia and Nepal actual employment has been rising. Other countries such as Fiji, Thailand, Indonesia and Malaysia alternate between positive and negative employment growth. Vietnam and China, however, have seen actual employment in agriculture falling since the turn of this millennium.

As shown in Figure 33, the decline in agricultural employment share has been rapid in some countries. Between 1970 and 2006 the employment share in agriculture shrank from 50.4 per cent to 7.7 per cent

in Korea and from 19.7 per cent to 5.1 per cent in Japan. Employment in agriculture also fell rapidly in the ROC, from 24.9 per cent in 1978 to 5.5 per cent in 2006. In all of these countries, the decline reflects an actual fall in employment in the agricultural sector. In China the share has declined from 70.5 per cent in 1978 to 43.4 per cent in 2006.

7.2 Industry Origins of Economic Growth

In Section 3.1 we see that, as a region, growth in Asia accelerated between 2000 and 2006, averaging 5.6 per cent per annum, up from 4.2 per cent between 1995 and 2000. In contrast, economic growth in the US slowed over the same period, from an average of 4.0 per cent per annum between 1995 and 2000 to 2.4 per cent between 2000 and 2006. Japan was the only economy with slower growth than the US between 2000 and 2006. China and India have been the two main drivers among the Asian economies, accounting for 49.1 per cent and 17.8 per cent of the region's growth, respectively. But looking at the

42 Gollin, Parente and Rogerson (2004) and Caselli (2005) demonstrated the negative correlation between employment share of agriculture and GDP per worker. They

showed that the agricultural sector was relatively large in poor countries and that agricultural labor productivity was lower than that in other sectors.

Figure 34: Industry Origins of Economic Growth, 1995–2000

Figure 35: Industry Origins of Economic Growth, 2000–2006

industry composition, the origins of economic growth in China and India are quite different. For the period 1978–2004, Bosworth and Collins (2007) found that China's economic growth was fueled by industry sector expansion,⁴³ whereas for India economic growth was led by service industry expansion. Our findings support their conclusion.

Figures 34 and 35 present the industry origins of average economic growth per annum in Asian countries for the periods 1995–2000 and 2000–2006, respectively. China was the fastest-growing economy in the region for both periods, accelerating from 8.2 per cent to 9.4 per cent on average per year. Manufacturing has been the main driver, making a stable

contribution to economic growth of around 47–48 per cent in both periods. The service sector, on the other hand, accounted for around 40–41 per cent of economic growth. Korea and Thailand are the two other countries where the manufacturing sector accounted for more than 40 per cent of economic growth in recent years. Such dominance of the manufacturing sector is above the norm, even though the contribution of this sector in most other Asian countries was also significant, accounting for a quarter or more of economic growth between 2000 and 2006.

Services play an equally, if not more, important role in Asian economic growth. Services made the biggest contribution to economic growth in all Asian

43 The industry sector in Bosworth and Collins (2007) is equivalent to manufacturing and other industries in this report.

Figure 36: Industry Contribution to Economic Growth, 1995–2000 and 2000–2006

countries except China and Lao PDR. Thailand is another exception, with manufacturing and services making roughly equal contributions. In contrast to the industry composition of China's growth, the story behind India's recent growth has been about services, accounting for 62.7 per cent of economic growth for the period 2000–2006, compared with 16.4 per cent from manufacturing. Modern information and communication technology has allowed India to take an unusual path in its economic development, bypassing a stage when manufacturing steers growth. Economic growth in the Asian Tigers was also dominated by the service sector, accounting for 64.4 per cent of growth in the ROC for the period 2000–2006, 73.1 per cent in Singapore and 108 per cent in Hong Kong (to counterbalance the negative growth of -4.3 per cent in manufacturing). Korea has a different decomposition from the other Asian Tigers, with manufacturing contributing 42.9 per cent of economic growth and 47.7 per cent from services. The split of contributions in Japan between manufacturing and services was 33.6 per cent and 72.2 per cent. This compares with the 10.2 per cent and 90.4 per cent split in the US. (For a more detailed breakdown of the service sector for Asian countries, see Figure 39.)

For some Asian countries, agriculture is still the biggest sector. The three countries where the agricultural sector has the largest share in total value added are Lao PDR, Nepal and Cambodia (Figure 29). For the period 2000–2006, agriculture in Nepal, Lao PDR and Cambodia had the highest contribution to economic growth among all Asian countries, accounting for 31.1 per cent, 22.9 per cent and 19.1

per cent of growth, respectively.

Comparing the industry origins of economic growth between the periods 1995–2000 and 2000–2006 is complicated by the impact of the Asian financial crisis of 1997–1998 on some of these countries. Indonesia and Thailand are considered to have been hit the hardest by the crisis. Both countries experienced little growth on average per annum between 1995 and 2000, with the service sector acting as a drag on the economy. The relative contributions by industry to economic growth have been stable in Asia between the periods 1995–2000 and 2000–2006 as a whole.

Figure 36 contrasts industries' contribution to economic growth for the periods 1995–2000 and 2000–2006, as well as between the US and the Asian average (which is an arithmetic mean of all countries, excluding Hong Kong due to data non-availability for 1995–2000). The relative contributions of manufacturing and services changed little between the two periods, i.e. around 27 per cent and 52 per cent, respectively. While the contribution of agriculture has been reducing, from 13.3 per cent to 9.4 per cent, that of other industries (i.e. mining, utilities and construction) has been rising, from 7.8 per cent to 11.6 per cent.

Comparing the Asian profile with that of the US, the major difference is in the contributions of agriculture and services. In the US, agriculture plays a much less significant role in economic growth, accounting for 1.9 per cent for 1995–2000 and 1.2 per cent in for 2000–2006, compared with 13.3 per cent and 9.4 per cent, respectively, in Asia. The US economic growth has been highly skewed towards

services, accounting for 75.4 per cent for 1995–2000 and 90.4 per cent for 2000–2006, compared with around 52 per cent in Asia.

7.3 Labor Productivity Growth by Industry

Section 6.2 discusses labor productivity performance in level terms, and identifies a large gap between Asia as a whole and the US. In 2006 Singapore was the only country that had a labor productivity level comparable to that of the US. Besides Singapore, the best performers in Asia achieved productivity levels that were at least 40 per cent of the US; yet Asia collectively was dragged down by a long tail of countries with labor productivity of less than 20 per cent the US level, pulling down the average performance to

14.7 per cent of that of the US for the APO20 and 11.6 per cent for Asia21. In growth terms, however, Asia's performance far exceeded that of the US, allowing the countries to close the level gap with the US gradually over time. Between 1995 and 2000 labor productivity growth in the APO20 was 0.7 per cent per annum on average, compared to 2.4 per cent in the US. Including China, the Asian average became 2.5 per cent. For the period 2000–2006 labor productivity growth accelerated to 1.7 per cent on average per annum for the APO20, or 3.9 per cent if China is included. Meanwhile, labor productivity growth decelerated to 1.3 per cent on average per annum in the US.

Table 11 presents cross-country comparisons in labor productivity by industry⁴⁴ for the period 2000–2006. The average labor productivity growth across countries was 1.7 per cent in agriculture, 3 per cent

⁴⁴ Labor productivity in Table 11 is defined simply as per-worker GDP at constant prices by industry (v_j). The industry decomposition of labor productivity growth for the whole economy (v) in Figures 37 and 38 is based on the equation $v = \sum_j \bar{w}_j v_j^*$ where the weight is the two-period average of value-added share. In this decomposition, the number of workers as a denominator of the labor productivity

(v_j^*) is adjusted, weighting the reciprocal of the ratio of the real per-worker GDP by industry to its industry average. Thus the industry contribution ($\bar{w}_j v_j^*$) is emphasized more in industries in which the per-worker GDP is higher than the industry average, in comparison with the impact of $\bar{w}_j v_j$ using the non-adjusted measure of labor productivity.

Figure 37: Industry Origins of Labor Productivity Growth, 1995–2000

Figure 38: Industry Origins of Labor Productivity Growth, 2000–2006

in manufacturing, 1.7 per cent in services and -0.4 per cent in other industries. These compare with US levels of 10.4 per cent in agriculture, 5.0 per cent in manufacturing, 1.2 per cent in services and -3.5 per cent in other industries. Note that China topped the ranking in Asia in all industry sectors except agriculture. Manufacturing remains the sector that offers the biggest potential for productivity growth, with the fastest achieved rate of 9–10 per cent per annum. However, as aforementioned, the potential for labor productivity growth in the service industries has been strengthened by information and communication technology in recent years, with an achieved rate of 8 per cent per annum.

Figures 37 and 38 show the industry origins of the average labor productivity growth per annum in the periods 1995–2000 and 2000–2006, respectively.

Not all Asian countries are included, because employment by industry sector is not available for some countries. Of the countries presented, China experienced the fastest growth in labor productivity for both periods. Not only that, productivity growth accelerated between the two periods, from 7.0 per cent to 8.4 per cent, compared with decelerated growth between the two periods in the US, from 2.6 per cent to 1.4 per cent.

Among all the industry sectors, other industries have made the least contribution to labor productivity growth in Asia, at around 8 per cent for the period 2000–2006. The contribution from agriculture was around 15 per cent over the same period, whereas manufacturing and services made very similar contributions of 39 per cent and 37 per cent respectively to labor productivity growth.

Figure 39: Composition of Labor Productivity Growth in the Service Sector, 2000–2006

The manufacturing sector has been traditionally the driving force behind productivity growth. This is certainly the case in most Asian countries. The manufacturing sector is particularly important in Korea, accounting for 76 per cent of the average annual labor productivity growth between 1995 and 2000 and 67.4 per cent between 2000 and 2006. For China, the figures were 63.7 per cent and 46.4 per cent, respectively. In Thailand, Malaysia and Japan manufacturing accounted for 55.9 per cent, 49.7 per cent and 49.4 per cent of respective average annual labor productivity growth between 2000 and 2006.

Traditionally, it has been difficult for the service sector to realize productivity growth, but modern advancements in information and communication technology have changed that. A lot of ICT-intensive users are in the service sector, which is capable of capturing the productivity benefits arising from ICT utilization. Recently, we have observed the growing importance of services in explaining productivity growth in the Western economies. In Asia the contribution from services is matching that of manufacturing. It was particularly prominent in India, accounting for 86.6 per cent of labor productivity growth during 2000–2006, while the contribution of manufacturing was negative for both periods. In Hong Kong nearly all the productivity growth was explained by the service sector. In the other Asian Tigers, services accounted for 50.6 per cent of labor productivity growth in Singapore and 42.7 per cent in the ROC between 2000 and 2006. Korea was the only Tiger where services made a relatively small contribution,

at 13.6 per cent. The contribution of services was also highly significant in Bangladesh and the Philippines over the same period.

Available data allow us to examine the service sector labor productivity growth of certain countries for the period 2000–2006 according to four subsectors: community, social and personal services; financing, insurance, real estate and business services; transport, storage and communication; and wholesale/retail trade and restaurants and hotels. The results are presented in Figure 39.⁴⁵ Except for the first subsector, the other three sectors are potentially IT-using industries. Tourism is also important in many of these countries, and is likely to impact the last subsector the most.

Among the countries presented, China experienced the fastest growth in service sector labor productivity at 7.7 per cent on average per annum, of which 60 per cent was explained by the three potential IT-using subsectors. India came second with a service sector labor productivity growth of 6.9 per cent, of which 85.6 per cent was explained by the three potential IT-using subsectors. With the exception of China, the Philippines and Malaysia, community, social and personal services played the least role in accounting for service sector labor productivity growth in all countries. In Vietnam, Cambodia, Hong Kong and Korea it even had a negative contribution. In the Philippines, Cambodia, Nepal and Mongolia, wholesale/retail trade and restaurants and hotels were a huge drag on service sector labor productivity growth, whereas it made a significant contribution

⁴⁵ Note that the measures for labor productivity in the service sector are different between Table 11 and Figure 39, due to the difference in methods to aggregate the measures from

industries within the service sector. A translog index is used in Figure 39, but not in Table 11 due to the lack of data in some countries.

Figure 40: Intra- and Inter-sectoral Effects in Labor Productivity Growth, 2000–2006

of 2.8 per cent and 2.2 per cent to labor productivity growth in Hong Kong and Indonesia respectively. Financing, insurance, real estate and business services were also significant in a number of countries, such as Hong Kong, China, India, the Philippines and Cambodia.

An improvement in aggregate labor productivity is a combination of two effects. It could reflect productivity gains within the industry sector (the intra-sectoral effect), and/or the extent of resource allocation taking place in the economy from low-productivity industries to high-productivity industries (the inter-sectoral effect). As the highly productive industries gain weight in the economy, they tilt the performance of the whole economy toward higher labor productivity. It is expected that

aggregate labor productivity growth is predominantly explained by the improved performance within each industry sector (the intra-sectoral effect), but a small result could still arise from the inter-sectoral effect, which is positive when high-performance industry is growing bigger in the economy. Figure 40 shows the decomposition of the intra- and inter-sectoral effects for the Asian countries,⁴⁶ where, as expected, the intra-sectoral effect dominates the overall labor productivity growth. Even so, the inter-sectoral effect has a significant impact on overall labor productivity growth in several countries. It can contribute up to 20.7 per cent to labor productivity growth in Pakistan and 11.4 per cent in Bangladesh, or can drag labor productivity growth down by up to 8.8 per cent in Iran.

46 Here, labor productivity growth is decomposed into the inter-sectoral (first part) and the intra-sectoral effect (second part, evaluated using the industry structure at the initial period) based on the equation $v = \sum_j (1/2)(u_j^{2006} - u_j^{2000})v_j^s + \sum_j u_j^{2000}v_j^s$ for the period 2000–2006, where labor productivity by industry v_j^s is defined in footnote 44. If there is an

increase of value-added share in industry with higher productivity growth from 2000 to 2006, the inter-sectoral effect would be positive. In the case of no change in value-added allocation among industries or of no difference in labor productivity growth among industries, this measure is zero.

Box 11: Level Comparison of TFP by Industry

A level comparison of TFP by industry is a hard task to implement due to a number of difficulties in the price comparison of KLEM (capital, labor, energy and materials) inputs and output. Thus Section 7.3 provides not a level comparison, but a growth comparison of labor productivity by industry. Recently, Jorgenson and Nomura (2007) provided a comparison of TFP levels between the US and Japan and allocated the gap to individual industries. They carefully distinguished the various concepts of PPP and measured them within the framework of a US-Japan bilateral input-output table. They also measured industry-level PPPs for KLEM inputs and output for 42 industries common to the US and Japan, based on detailed estimates for 164 commodities, 33 assets, including land and inventories, and 1,596 labor categories. They found that the US-Japan productivity gap shrank during three decades of rapid Japanese economic growth between 1960 and 1990. The Japanese manufacturing sector achieved parity with its US counterpart by the end of the period. With the collapse of the Japanese economic bubble at the end of the 1980s, the US-Japan productivity gap reversed course and expanded to 79.5 per cent by

2004. This can be attributed to rapid productivity growth in the IT-producing industries in the US during the late 1990s and the sharp acceleration of productivity growth in the IT-using industries in the US between 2000 and 2004.

Figure B11 presents industry-level TFP gaps and the contributions of each industry to the overall TFP gap for 2004. Industries are ordered by the magnitude of their contributions to the TFP gap. The first column gives the US-Japan TFP gap, defined as the ratio of TFP in Japan to TFP in the US. Note that TFP gaps for public administration and household sectors are zero by definition, since the outputs of these industries consist entirely of capital inputs. The second column gives the contribution of each industry to the aggregate TFP gap, using Domar weights. In 2004 motor vehicles made the largest contribution to Japanese TFP, relative to the US. Wholesale/retail trade and other services, two industries largely sheltered from international competition, accounted for 25.1 and 22.5 per cent, respectively, of the lower TFP level of the Japanese economy. Allocating the productivity gap to its origins at the level of industries is the first step in formulating policies to reduce the gap.

Figure B11: Industry Origins of the US-Japan TFP Gap, 2004

Data Sources

Most of the data for APO member economies have been prepared by the national experts of each country. A list of the national experts is given in Section 1.2. GDP and industry GDP are based on the System of National Accounts estimated in each country. Employment data have been constructed by using some statistics listed in Table 12. For those countries where we could not find the primary statistics, we refer to the publications from which data have been taken (e.g. statistical yearbooks). These data provided by the national experts are supplemented by the use of external data sources such as CEIC Data Company Ltd, *ILO Yearbook of Labor Statistics* (<http://laborsta.ilo.org>), World Bank *World Development Indicators*, UN data (National Accounts Official Country Data – <http://data.un.org>) and *Key Indicators* of the Asian Development Bank (www.adb.org/documents/books/key_indicators).

There are three reference countries, for which the authors collected and constructed data. For China, we use multiple data sources. GDP for the whole economy, industry GDP, final demands and employment

are taken from CEIC Data Company Ltd. Income data are taken from *China National Income 1952–1995* and *China Statistical Yearbook*. Time series data of GFCF during 1950–2006 are constructed by the authors. Main references for GFCF construction are *Statistics on Investment in Fixed Assets of China 1950–2000*, *China Statistical Yearbook* and 1987, 1992, 1997, 2002 *Input-Output Tables of China*. Multiple data sources for manufacturing, electrics and trade data from *China's Customs Statistics* are also utilized.⁴⁷ The data source for the EU15 is OECD.Stat (<http://stats.oecd.org/WBOS/index.aspx>). The data for the US are taken from the website of the Bureau of Economic Analysis (www.bea.gov) and the UN data website.

Tax data of member economies are supplemented by the IMF's Government Finance Statistics. From its tax revenue data, “taxes on goods and services” and “taxes on imports” are used for calculating taxes on products. From its expenditure data, “subsidies” are taken. Data taken from GFS play a key role in adjusting GDP at market prices to GDP at basic prices.

Sources for Employment Data

Bangladesh	Labor Force Survey, Population Census
Cambodia	Socio-economic Survey, Labor Force Survey
ROC	Yearbook of Manpower Survey Statistics in Taiwan Area, Taiwan Statistical Data Book
Fiji	Annual Employment Survey, Population Census, Estimates by FIBOS (Fiji Islands Bureau of Statistics)
India	Census of India
Indonesia	Labor Situation in Indonesia
Iran	Population Census
Japan	Labor Force Survey, National Accounts
Korea	Census on Basic Characteristics of Establishment, Economically Active Population Survey, Monthly Labor Survey
Lao PDR	ADB Key Indicators
Malaysia	Economic Report (various issues), Malaysia Economic Statistics Time Series, Labor Force Survey Report
Mongolia	Mongolian Statistical Yearbook
Nepal	Population Census
Pakistan	Pakistan Economic Survey
Philippines	Labor Force Survey, Philippines Statistical Yearbook
Sri Lanka	Central Bank of Sri Lanka Annual Report
Thailand	Labor Force Survey
Vietnam	Estimates by General Statistics Office

47 Soyoen Myung (Graduate School of Keio University) provided us with excellent research assistance in constructing a Chinese database.

About the APO

MISSION

The Asian Productivity Organization (APO) was established on 11 May 1961 as a regional intergovernmental organization. Its mission is to contribute to the socioeconomic development of Asia and the Pacific through enhancing productivity. The APO is nonpolitical, nonprofit, and nondiscriminatory.

MEMBERSHIP

APO members are: Bangladesh, Cambodia, Republic of China, Fiji, Hong Kong, India, Indonesia, Islamic Republic of Iran, Japan, Republic of Korea, Lao PDR, Malaysia, Mongolia, Nepal, Pakistan, Philippines, Singapore, Sri Lanka, Thailand, and Vietnam.

KEY ROLES

The APO seeks to realize its objective by playing the roles of think tank, catalyst, regional adviser, institution builder, and clearinghouse for productivity information.

ORGANIZATION

The supreme organ of the APO is the Governing Body. It comprises one Director from each member country designated by their respective governments. The Governing Body decides on policies and strategies of APO programs and approves its budgets, finances, and matters relating to membership.

Each member country designates a national body to be its national productivity organization (NPO). NPOs are either agencies of the government or statutory bodies entrusted with the task of spearheading the productivity movement in their respective countries. They serve as the official bodies to liaise with the APO Secretariat and to implement APO projects hosted by their governments.

The Secretariat, based in Tokyo, Japan, is the executive arm of the APO. It is headed by the Secretary-General. The Secretariat carries out the decisions, policy directives, and annual programs approved by the Governing Body. It also facilitates cooperative relationships with other international organizations, governments, and private institutions.

The APO Secretariat has four functional departments: Administration and Finance, Research and Planning, Industry, and Agriculture.

PROGRAMS AND ACTIVITIES

APO's programs cover the industry, service and agriculture sectors, with special focus on socioeconomic development, development of small and medium enterprises, human resources management, productivity measurement and analysis, knowledge management, production and technology management, information technology, development of NPOs, green productivity, integrated community development, agribusiness, agricultural development and policies, resources and technology, and agricultural marketing and institutions.

Its activities include researches, forums, conferences, study meetings, workshops, training courses, seminars, observational study missions, and demonstration projects.
