An Equilibrium Model of Continually Heterogeneous Labor Market

Keiichiro Obi

Keio Economic Observatory Keio University

1. Introduction

In this paper a model of the labor market, where wage differentials among the firms of various scales exist, is presented. The term “firm of various scale” is used to indicate that the heights of marginal productivity curves for labor are different for different firms.

If the labor market is competitive, a unique wage rate prevails so long as the labor force is homogeneous from the firm’s point of view. If the labor force is heterogeneous, but can be split into three groups A, B and C, where firm a exclusively recruits workers from group A and the members of group A exclusively apply to a, and so on, we have three independent labor markets and the notion of non-competing groups can be applied to determine wages within each market. However, if the firms a, b and c respectively recruit among all the members of the groups A, B and C simultaneously, then the notion of non-competing groups is not applicable to the labor market. Since the actual labor market we observe has such a nature, we need to construct a model which can describe the performance of a competitive and heterogeneous labor market.

By heterogeneity, we mean the existence of various grades (or labor que) among applying workers from the firm’s point of view. The grades or ordering of applicants might be directly or indirectly correlated with their work experience, educational background, age, and/or sex. However, even if those characteristics or qualities are controlled, there may yet exist some ordering or differences in grades of applying workers. In fact, statistical data shows that there are wage differences among workers of firms of different sizes when controlling for these characteristics of the workers.

This observed fact suggests that firms recognize different grades among workers of the same age, sex, work experience, and/or educational backgrounds. Any reason for the paying of higher wages by large firms, whose labor productivities are higher than smaller ones, cannot be found as long as the grades of workers are the same across firms. In fact, large scale firms with higher productivities offer comparatively favorable work conditions (higher wages and shorter hours of work) and as a result attract many applicants of various grades. The firms recruit what they perceive as the most favorable ones among those who applied. Smaller firms with lower productivity can offer only less favorable terms and recruit among the residual applicants who fail to be employed by the large scale firms. This is the common experience of high school and college graduates in Japan.

In the following section we present a model of the labor market making use of the notion of grades\(^1\) of labor in order to realistically approximate the labor market in Japan.

---

\(^1\)Reprinted and corrected from *Keio Economic Observatory Occasional Paper E.No.14* (January 1995). This paper was presented at The International Symposium on Economic Modeling, Athens 1993.

\(^2\)The notion of this kind, that is, labor que, is used in L.C. Thurow [10]
The model is suitably simplified. Although the labor supply actually consists of members of self-employed households (e.g., farmers' households) and employee households whose principal earners are employees, only the latter type of household is taken into account. As well, the investment behavior of firms is not explicitly treated. These simplifications will not impair the basic characteristics of the model which remain sufficiently autonomous. The performance of the model is tested by numerical examples and by the application to Japanese data.

Models of wage and employment determination with respect to a firm (or a group of firms) have been developed elsewhere. In this kind of model, individual labor supply and labor demand functions for a firm are assumed; that is, the notion of a kind of local labor market is introduced in the models. However, the relation between the individual labor supply function for the specific firm considered and the supply function of the market as a whole is not explicitly discussed. Such an individual supply function is, to some extent, an ad hoc relation just as is the individual demand function for a firm is product in an oligopolistic market. The wage level of the firm considered and the average wage level of other firms appear as explanatory variables of the individual labor supply function (The ratio of the both variables is adopted in some cases).

Elasticities of labor supply with respect to those variables or coefficients of those variables for each firm change, reflecting change in the conditions of the labor market as a whole including changes in the degree of competition, the labor suppliers' conjecture with respect to the recruitment policy of firms other than the firms to which the suppliers are applying. However, the mechanism of such interdependent changes of elasticities or coefficients of individual supply function has not been clarified. In this sense, models using individual supply functions lack autonomy.

Individual labor supply functions for each firm are not used in the model presented below. Instead, two basic relations are introduced. Instead of an individual supply function for a firm, which describes the relation between the number of applicants for the specific firm and the wage rate the firm offers, we use the labor supply function for the whole market describing the quantity of labor supplied, the wage rate being given. That is, the supply function used in the following model does not specify the distribution of the quantity of labor supplied among firms. The distribution itself is determined by the model including firm demand functions for labor.

2. Basic Equations of the Model

2.1. Distribution Function of Grades of Labor

Let the indicator of the grade of the worker be $G_i$, where $i = 1, 2, ..., m$.

and $m$ is the total number of people of working age. The range of $G_i$ is supposed to be

$$\varepsilon \leq G_i \leq 1$$

where $\varepsilon$ is some positive small number.

The cumulative distribution (cumulative from the top of $G$, where $G = 1$) function of $G$ is designated by $\nu(G)$ and the density distribution by $\nu'(G)$.

---

\(^2\)C.A. Pissarides [9]
2.2. Labor Supply Probability Function

Suppose among \( n \) persons, \( n' \) persons accept the employment opportunity at wage rate \( w \), and assigned hours of work \( h \), offered by firms. The ratio \( n'/n \) is the supply ratio with respect to the employment opportunity.

\[
\text{Plim}_{n \to \infty} n'/n = \mu
\]

is defined as the supply probability, which is a function of \( w \) and \( h \).

2.3. Distribution of Minimum Supply Price of Labor

The minimum supply price of labor\(^3\) is defined as a critical wage rate below which suppliers reject the employment opportunity, assigned hours of work \( h \) being given. The minimum supply price of labor (MSPL) is denoted by \( w \). Any supplier’s level of MSPL depends on following three factors:

a) the shape of his/her income-leisure preference curve,

b) the level of his guaranteed income \( X_g \) which he/she can obtain without working (e.g. principal earner’s income is a guaranteed income for non principal earners),

c) hours of work assigned by firms, \( h \).

Hence, we have

\[
w^i = w(x^i_g, h^i, \alpha^i) \quad i = 1, 2, \ldots, n
\]  

(1.1)

where \( \alpha^i \) stands for the set of preference parameters of the \( i \)th supplier. \( x^i_g \) and \( h^i \) can be regarded as exogenous variables for the \( i \)th supplier. The value of \( \alpha^i \) is specific to \( i \)th supplier; that is, the value of \( \alpha^i \) differs among each of the \( n \) suppliers. Hence, we have the density distribution function \( \phi(\alpha) \).

Now, suppose a group of persons have the same level of guaranteed income \( \bar{x}_g \); that is,

\[
x^i_g = x^{i+1}_g = \bar{x}_g
\]  

(1.2)

From (1.1), (1.2) and \( \phi(\alpha) \), we have

\[
g_f(\bar{x}_g | \bar{x}_g, h) \]

\(\text{Notation of reservation wage(RW) is given in Heckman[2]. MSPL is another definition of a kind of RW, because MSPL is defined by assuming } h \text{ is a parameter which is assigned by the firm. In the modern employee labor market (in contract to self employed work), hours of work are assigned by the employer(firm). The employees have some minimal leeway as they can reduce or increase the hours worked to some extent. However, a complex array of social, psychological, and institutional factors usually produces a situation where excessive absenteeism etc. will result in dismissal. The analogous situation exists with respect to "overtime". Analysis of the MSPL of labor using an income-leisure preference function assuming maximization behavior is shown in Kichihiro Obi[5],[6],[7], and T.Miyayashi[4]}

\(^3\)The notion of reservation wage(RW) is given in Heckman[2]. MSPL is another definition of a kind of RW, because MSPL is defined by assuming \( h \) is a parameter which is assigned by the firm. In the modern employee labor market (in contract to self employed work), hours of work are assigned by the employer(firm). The employees have some minimal leeway as they can reduce or increase the hours worked to some extent. However, a complex array of social, psychological, and institutional factors usually produces a situation where excessive absenteeism etc. will result in dismissal. The analogous situation exists with respect to "overtime". Analysis of the MSPL of labor using an income-leisure preference function assuming maximization behavior is shown in Kichihiro Obi[5],[6],[7], and T.Miyayashi[4]
which is the density distribution function of MSPL, \( h \) for brevity being assumed a common value for all persons considered. Subscript \( f \) and \( \phi \) denote the fact that the analytical form of the function \( g \) depends on \( f \) and \( \phi \). Integration of \( g \),

\[
\mu = \int_{w = 0}^{w} g(w \mid \overline{x}_g, h) dw = \mu(w \mid \overline{x}_g, h),
\]

(1.4)
gives the supply-probability function \( \mu \) of the group of persons with \( \overline{x}_g \) and \( h \).

Multiplying by \( n \), the number of persons in the group, we have the number of suppliers \( L^s \), namely,

\[
L^s = n \mu(w \mid \overline{x}_g, h),
\]

(1.5)

When \( x_g \) and \( h \) are distributed as a joint density distribution

\[
\psi(x_g, h),
\]

(1.6)
we have

\[
\mu(w) = \int_{w = 0}^{w} \int_{x_g = c}^{d} \int_{h = a}^{b} g(w, x_g, h) \psi(x_g, h) \cdot dh \cdot dx_g \cdot dw
\]

(1.7)
where \( a, b, c, d \) and \( e \) are the values standing for regions of integration for the relevant variables, \( h, x_g \) and \( w \).

3. The Outline of the Model

Let the production function of the \( i \)th sector (or firm) be

\[
Q_i = F(L_i, \overline{G}_i, A_i) \quad (i = 1, 2, \ldots, n)
\]

(2.1)
where \( A \) and \( \overline{G} \), respectively, stand for the set of firm parameters and the index of the grade of workers employed in the \( i \)th sector. Further, \( \overline{G}_i \) can be written as

\[
\overline{G}_i = G_i^{\text{min}}(G_i^{\text{max}})
\]

(2.1')
where \( G_i^{\text{max}} \) and \( G_i^{\text{min}} \) are indicators of the highest grade of workers (most preferable workers among applicants from the firm’s point of view) and the lowest grade of workers.

It is supposed that

\[
\frac{\partial F}{\partial \overline{G}_i} > 0, \quad \frac{\partial F}{\partial L_i} > 0.
\]

Let the supply probability equation (1.7) be

\[
\mu = \mu(w, \overline{\lambda})
\]

(2.2)
where $\overline{\lambda}$ is a set of parameters of individuals, and for the sake of brevity assigned hours of work, $h$, is excluded and the guaranteed income level $x_0$ is supposed to be included in the set $\overline{\lambda}$.

The (cumulative) distribution function of $G$ is denoted by

$$\nu_G = \nu(G) \quad (2.3)$$

where

$$\varepsilon \leq G \leq 1 \quad (2.4)$$

An indirect method of observation of $G$ is discussed in section 4.1.3.

Let us suppose that the analytical form of the function $\nu$ is common to all the sectors under consideration. Hence, by letting the number of potential suppliers be $N$, the number of suppliers with grade $G$ and over, $N_G$, is given by

$$N_G = N \cdot \nu_G = N \cdot \nu(G) \quad (2.5)$$

The number of suppliers with grade $G$ and over going to the $i$th sections, $L_i^G$, is written as

$$L_i^G = N \cdot \nu(G) \cdot \mu(w_i, \overline{\lambda}) \quad (2.6)$$

where $w_i$ stands for the wage rate offered by the $i$th sector.

### 3.1. Behavior of the Leader

Imagine a sector (or firm) which offers the most favorable wage in comparison to other sectors in order to attract a number of potential suppliers. This sector can recruit workers of higher grades comparing to other sectors which offer less favorable working conditions. We shall call this sector a leader sector (firm) or a leader for short. Residual sectors are followers. Among those residual sectors, we can distinguish leaders and followers in accordance with the wage differentials each sector is willing to pay. That is, if we have three sectors with wage rates $w_1, w_2$ and $w_3$ where $w_1 > w_2 > w_3$, sector 2 plays the role of the follower of sector 1, while sector 2 plays the role of leader of sector 3. Follower sector 2, against leader sector 1, recruits workers with relatively higher grades amongst residual applicants which the leader has left for followers to employ because those applicants are not fully suitable for employment from the leader's point of view. Sector 2 as a leader against sector 3 will again leave undesirable labor suppliers. This pattern can be viewed as continuing indefinitely, $i$th sector 3 acting as a leader to sector 4, and so on.

Let us imagine a labor market which consists of two sectors to simply present the basic characteristics of the model, where one of the sectors is able to attain a given level of production $Q_k$ $(k = 1, 2)$ by varying $G_i$ and $L_i$ in the production function (2.1).

The distribution function (2.5), $N \cdot \nu(G)$, is depicted in the fourth quadrant in Figure 1. The curve $GN$ is the cumulative distribution curve from the top labor grade $G(=1)$. Suppose firm $\ell$ (we denote leader by $\ell$) wishes to recruit workers with grades higher than $G^\text{min}_\ell$. In this case, the labor supply curve for firm $\ell$ can be depicted by curve $S_i^\ell$ in the 1st quadrant. This curve stands for equation (2.6) where $G^\text{min}$ is inserted for $G$. Now, $G^\text{max}(=1)$ and $G^\text{min}$ being given for the firm $\ell$, the demand curve for labor is derived from
the production function \((2.1)\) and \((2.1')\) by applying the condition of cost minimization. This is depicted by curve \(D_\ell\) in the first quadrant. The intersection of the supply curve \(s_\ell s'_\ell\) and \(D_\ell\) gives the wage rate \(w_\ell\) and the demand for labor \(L_\ell\) by firm \(\ell\) necessary to attain the given level of production \(Q_\ell\).

If firm \(\ell\) were content to recruit workers with lesser grades, e.g., \([G^\min] < G^\min \ell\), the curve \(s_\ell s'_\ell\) would be less steep and stretched to the right. Hence, the required grade of workers would be less and the number of workers employed would increase. At any rate, given the production function \((2.1)\), the grade distribution function \((2.3)\), and the supply probability function \((2.2)\), the number of workers and the required grade to attain production level \(Q_\ell\) are determined by the procedure of cost minimization.

From \((2.5)\) and \((2.2)\) the number of potential applicants with grade \(G^\min \ell\) and over, \(L^\min \ell\), is given by

\[
L^\min \ell = N_\ell \cdot G^\min \ell \cdot \mu = N \cdot \nu(G^\min \ell) \cdot \mu(w_\ell, \bar{x}) \tag{2.6'}
\]

which is a function of \(w_\ell\). Eq.(2.6') is depicted by the curve \(s_\ell s'_\ell\) in Figure 1.

**Figure 1**

We have, for the leader, \(G^{max} = 1\) in \((2.1')\). Hence, \((2.1')\) is written as \(G^\ell = G^\ell(G^\min \ell, 1)\). Substituting this function and \((2.6')\) into \((2.1)\) gives the leader’s production function.

\[
Q_\ell = F[N \cdot \nu(G^\min \ell) \cdot \mu(w^\min \ell, \bar{x}), G^\ell(G^\min \ell, 1), \Lambda_\ell], \tag{2.1''}
\]

where the subscript \(i\) in \((2.1)\) has been replaced by \(\ell\) to denote that eq. \((2.1'')\) refers to the leader. Definition of cost is given by

\[
C_\ell = C^\ell_0 + w_\ell \cdot L^\min \ell = C^\ell_0 + w_\ell N \cdot \nu(G^\min \ell) \cdot \mu(w_\ell, \bar{x}) \tag{2.7}
\]

where \(C^\ell_0\) stands for capital cost which is regarded as given.
An Equilibrium Model of Continually Heterogeneous Labor Market

We can obtain \( w_\ell \) and \( G_{\ell}^{min} \) by minimizing \( C_\ell \) in (2.7) under the constraint (2.1'), \( Q_\ell \) being given:

Letting

\[
\psi_\ell = C_\ell + k\{Q_\ell - F[N \cdot \nu(G_{\ell}^{min}) \cdot \mu(w_\ell, \overline{\lambda}), \overline{\sigma}(G_{\ell}^{min}, 1), A_\ell]\}
\]

(2.8)

where \( k \) is Lagrangian multiplier, and \( C_\ell \) is given by (2.7), we have

\[
\frac{\alpha \psi_\ell}{\partial G_{\ell}^{min}} = \frac{\partial \psi_\ell}{\partial w_\ell} = 0.
\]

(2.9)

Solving (2.1') and (2.9) simultaneously for \( G_{\ell}^{min} \) and \( w_\ell \), we obtain,

\[
G_{\ell}^{\ast} = G_{\ell}^{\ast}(\overline{\sigma}_0, \overline{\lambda}, A_\ell, Q_\ell)
\]

(2.10)

and

\[
w_\ell^{\ast} = w_\ell^{\ast}(\overline{\sigma}_0, \overline{\lambda}, A_\ell, Q_\ell)
\]

(2.11)

where \( \overline{\sigma}_0 \) is a set of parameters in the grade distribution function (2.3). Equations (2.10) and (2.11) give optimal values for \( G_{\ell}^{min} \) and \( w_\ell \) both minimizing cost \( G_{\ell} \) for the given production level \( Q_\ell \). The solution for employment \( L_\ell \) can be calculated by substituting (2.10) and (2.11) into (2.6) for \( G \) and \( w \) respectively. We shall call the number of workers thus obtained, and \( G_{\ell}^{\ast} \) and \( w_\ell^{\ast} \) given by (2.10) and (2.11) as the “leader solution”.

3.2. Follower’s Behavior

The highest grade of workers attainable to the follower is \( G_{f}^{min} \) which is the lowest grade for the leader. Let the lowest grade of people in the group of potential applicants for the follower be \( G_{f}^{min} \). The number of people with grades between \( G_{f}^{min} \) and \( G_{\ell}^{min} \), which we denote by \( N_{G_{f}^{min}} \), is given by

\[
N_{G_{f}^{min}}^{\ast} = N \cdot \nu(G_{f}^{min}) - N \cdot \nu(G_{\ell}^{min}),
\]

(2.12)

which is shown by the length of \( N_{G_{f}^{min}}^{\ast} \sim N_{G_{\ell}^{min}}^{\ast} \) in Figure 1. Hence, the number of suppliers to the follower \( L_{G_{f}^{min}}^{\ast} \) is written as

\[
L_{G_{f}^{min}}^{\ast} = N_{G_{f}^{min}}^{\ast} \cdot \mu = N[\nu(G_{f}^{min}) - \nu(G_{\ell}^{min})] \cdot \mu(w_f, \overline{\lambda}).
\]

(2.13)

Substituting (2.13) into (2.1), we have the production function of the follower:

\[
Q_f = F[N \cdot \nu(G_{f}^{min}) - \nu(G_{\ell}^{min})] \cdot \mu(w_f, \overline{\lambda}), \overline{\sigma}_f(G_{f}^{min}; G_{\ell}^{\ast}, A_f)
\]

(2.14)

where \( A_f \) is the set of parameters of the follower’s production function, and \( G_{\ell}^{\ast} \) is given by (2.10). The definition of follower’s cost \( C_f \) is given by

\[
C_f = C_0^f + w_f \cdot L_f = C_0^f + w_f \cdot N[\nu(G_{f}^{min}) - \nu(G_{\ell}^{min})] \cdot \mu(w_f, \overline{\lambda}).
\]

(2.15)
where \( C^f_0 \) is capital (fixed) cost and (2.13) is substituted for \( L_f \).

Let us minimize \( C_f \) in (2.15) under the constraint of (2.14) where the level of \( Q_f \) is given.

\[
\psi_f = C_f + j[Q_f - F(\cdot)].
\] (2.16)

where \( j \) is the Lagrangean multiplier.

The minimization condition is as follows.

\[
\frac{\partial \psi_f}{\partial G^\text{min}_f} = \frac{\partial \psi_f}{\partial w_f} = 0.
\] (2.17)

Solving (2.17) for \( G^\text{min}_f \) and \( w_f \), we have

\[
G^*_f = G^*_f(\pi_0, \lambda_1, A_f, Q_f, G^*_f)
\] (2.18)

\[
w^*_f = w^*_f(\pi_0, \lambda, A_f, Q_f, G^*_f).
\] (2.19)

where \( G^*_f \) is already given by the leader’s solution (2.10). \( L_f \) can be obtained from (2.13) by inserting (2.18) and (2.19). We shall call this employment level and (2.18) and (2.19) the “follower’s solution”.

### 3.3. Succession Equilibrium

When we have three or more firms (sectors), we can successively apply the above leader-follower relationship. We shall call the state of market shared by firms (sectors) playing the role of leaders and followers successively as succession equilibrium. Let us suppose two firms are in a state of succession equilibrium. Now, suppose relative or absolute changes in the production level of the leader cause a “leader’s solution” with a wage rate \( w \) lower than the follower’s. Then, of course, the initial state of the market cannot be sustained. A new leader-follower relation has to be established. The former follower succeeds to the position of leader and the former leader now becomes a follower. However, alternative cases could be considered. If the initial leader expects that he will not be able to hold the position of leader without augmenting the marginal productivity of his workers and if he finds losing his leader position is not profitable, he might invest in capital to augment his workers’ productivity.

### 3.4. Conditions for Succession-Equilibrium in Labor Market

Let us concentrate on the leader unit \( A \) and the successive follower unit \( B \). By definition we have \( w_A > w_B \) and \( G_{A}^\text{min} > G_{B}^\text{min} \). We shall examine the condition that guarantees a stable structure of wage differentials. We use the term “succession equilibrium” to characterize a labor market with stable wage differentials.

The necessary condition for succession equilibrium is that

\[
w^*_\ell > w, \quad (2.20)
\]
An Equilibrium Model of Continually Heterogeneous Labor Market

where \( w_t \) and \( w \) stand for leader \( A \)'s and follower \( B \)'s wage rate respectively. Necessary and sufficient conditions read as follows. (Precise discussion is given in Obi[7])

(a) Letting \( A \) and \( B \) be the leader and follower respectively, when (2.20) holds, the leader-follower relationship is stable, if the following condition is satisfied.

(a.1) Let \( B \) be a leader instead of \( A \), \( A \) being a follower, and compute the leader solution for \( B \). Let the solution for the wage rate be \( w_t \). Compute the follower solution for \( A \). Let the solution be \( w \). Then suppose (2.20),

\[
w_t > w
\]

does not hold. This is the necessary and sufficient condition for stable successioneqilibrium.

(a.2) When the leader-follower relationship between \( A \) and \( B \) is inverted in the computation procedure (a.1), if (2.20) holds in this case as well, then the leader-follower relationship cannot be stable. Now suppose that the analytical forms of the production function and the grade-distribution function are true and the estimated parameters are correct. Further suppose that numerical values of the set of parameters and the production levels of production unit \( A \) and \( B \) are such that they generate the unstable case mentioned above. On the other hand suppose, in the real labor market, a stable wage differential between unit \( A \) and \( B \) is observed. Then it must be considered that the leader-follower relationship between \( A \) and \( B \) is sustained by factors other than those already considered; e.g. historical or random factors. Hence, the observed leader-follower position of \( A \) and \( B \) will be inverted whenever those factors change.

(b) Letting \( A \) and \( B \) be the leader and follower respectively, when (2.20) does not hold, the inverse leader-follower relationship is stable so long as the following condition is satisfied.

(b.1) Let \( B \) be a leader instead of \( A \) and compute the leader solution for \( B \). Let the solution for the wage rate be denoted by \( w_t \). Compute the follower solution for \( A \). Let the solution be denoted by \( w \). Next suppose (2.20)\( w_t > w \), does not hold. In this case, it can be said that the set of estimated parameters of the model is not correct or the model itself is at fault.

(b.2) When the leader-follower relationship between \( A \) and \( B \) is inverted in the computation procedure, if (2.20) holds, then the leader-follower relationship is stable. \( B \) and \( A \) being the leader and follower respectively. However, this case, (b.2), is substantially equivalent to case (a.1), and the indepent cases are (a.1), (a.2) and (b.1). Hence, (a.1) is the necessary and sufficient condition for the stability of successive equilibrium.

3.5. Simple Model

We shall specify the analytical form of production functions (2.1) and (2.1') as

\[
Q_i = b_i L_i^\eta_i (G_i)^{\gamma_i}, \quad \sigma_i > 0, \quad \gamma_i > 0 \quad (i = 1, 2, \ldots),
\]

(3.1)
where $G_i$ and $G_{i+1}$ respectively stand for the highest and the lowest values of $G$ among the workers the $i$th firm employs. Let $i = \ell, f$, where $\ell$ and $f$ respectively stand for leader and follower.

Simplifying the distribution function $\nu(G)$ without impairing the basic characteristics of the model, we use

$$\nu(G) = \nu_0 + \nu_1 G,$$ (3.2)

where $\nu_0$ and $\nu_1$ are parameters.

We specify the supply-probability equation (2.2) as a linear function of $w$

$$\mu = \lambda_0 + \lambda_1 w,$$ (3.3)

where as shown later

$$\lambda_0 < 0, \quad \lambda_1 > 0 \quad \text{and} \quad 0 \leq \mu \leq 1$$ (3.4)

3.6. Numerical Experiments

3.6.1. Simulation System

We shall present a few numerical experiments to examine the workability of the successive equilibrium model. Let the number of production units (or firms) be two, unit 1 and 2. Numerical values of the parameters are assigned as follows.

$$\alpha_1 = \alpha_2 = 1, \quad \gamma_1 = 0.4, \quad \gamma_2 = 0.9, \quad b_1 = b_2 = 1,$$

$$\nu_0 = 1, \quad \nu_1 = -1, \quad \nu_0 = -0.5, \quad \lambda_1 = 0.01, \quad N = 10,000$$

Suffix 1 and 2 stand for unit 1 and 2 respectively. The elasticity of production with respect to grades for unit 2, $\gamma_2$, is larger than that for unit 1.

The levels of production of unit 1 and 2 are experimentally given as shown in the first and second columns of Table 1a through 1g. These are exogenous variables in the simple model under consideration.

(a) In Table 1a, $Q_2$ is increased from 150 to 300, $Q_1$ being constant. In this case the computation process revealed the succession-equilibrium was stable and a stable leader-follower relationship holds as is shown in the table; i.e. unit 2 and 1 are the leader and follower respectively. The wage differential $w_2/w_1$ increases.

(b) In the second case, $Q_1$ and $Q_2$ were increased with a common rate of growth starting from $Q_1 = Q_2 = 160$, as shown in Table 1b. The leader-follower relationship does not alter. The wage differential decreases, unlike that of case (1). It can be seen that the increase in the wage differential in case (1) stems from the growth and stagnation of production of unit 2 and 1 respectively.
(c) In Table 1a, $Q_2$, the production of unit 2 which has a larger value for $\gamma$ compared to unit 1, was increased. In contrast to this, production $Q_1$ of unit 1 is increased, $Q_2$ being held constant at 150, in Table 1c. For the values of $Q_1 = 160, \ldots, 190$, unit 2 occupies the position of leader, while case (b,1) appears when $Q_1$ exceeds 200; that is, we do not have a consistent solution for $Q_1 \geq 200$ and $Q_2 = 150$.

(d) Next, in order to clarify the response of production unit 2 against production unit 1 with $Q_1 = 200$, we tentatively assigned $Q_2$ values in the range $38 \leq Q_2 \leq 750$. (See Table 1d). It was found that the leader position switches if $Q_2 > 47$. The altered leader-follower relationship is stable for $Q_1 = 200$ and $38 < Q_2 < 47$.

(e) A test analogous to (d) is shown in Table 3e. Here, $Q_2$ is held constant at 150, while $Q_1$ is varied between $63 \leq Q_1 \leq 1250$. The leader role switches when $Q_1$ reaches 1250.

(f) Analogous to (e), we take $Q_1 = 250$ and $38 < Q_2 < 750$. For $Q_2 > 250$, unit 2 and 1 play the leader and follower respectively. If $Q_2 \leq 54$, the relationship alters. Between $Q_2 = 54$ and $Q_2 = 250$, we do not have stable succession equilibrium (consistent solutions).

(g) Analogous to (f), we vary $Q_2$ between 38 and 750, $Q_1$ being 300. For $Q_2 > 250$, unit 2 and 1 are the leader and follower respectively. However, for $Q_2 \leq 63$ this relationship alters.

3.6.2. The Ranges of Production which Guarantee Stable Succession Equilibria

The ranges for production of sectors 1 and 2, which guarantee stable succession equilibria, are depicted in Figure 2. The thick lines and dotted lines or segments respectively stand for the ranges where succession equilibria are guaranteed and not guaranteed. Thus, it can be seen that the hatched area represents (a part of) the unstable regions.
Thick lines and segments stand for the region where stable succession equilibrium holds. Attached numbers stand for leader-follower relations, e.g., 2–1 states that unit 2 and 1, respectively, play the role of leader and follower.

An Alternative Simple Model

Basic Equations

Production function

We shall specify the analytical form of production functions (2.1) as

\[ Q_i = \beta_i L_i. \] (3.1a)

Let the cost function of ith firm (or sector) be

\[ C_i = \psi_i(\overline{G}_i, L_i) + w_i L_i \] (3.1'a)

where \[ \overline{G}_i = (G_i+1 \cdot G_i)^{\frac{1}{2}}, G_i+1 < G_i \]

where \( G_i \) and \( G_{i+1} \) respectively stand for the highest and the lowest values of \( G \) among the workers the ith firm employs.

The distribution function of grade indicator

Simplifying the distribution function \( \nu(G) \) without impairing the basic characteristics of the model, we use

\[ \nu(G) = \nu_0 + \nu_1 G, \] (3.2)

where \( \nu_0 \) and \( \nu_1 \) are parameters. \( \nu(G) \) is the ratio of the number of potential applicants with grade \( G \) and over to the total number of potential applicants (the number of the people of working age). The magnitudes of \( G \)'s the potential supplier with the highest and lowest grade among all potential suppliers are respectively defined to equal unity and \( \varepsilon, \varepsilon \) being some small positive number. Hence, we have

\[ \nu(G) = 1 \quad \text{if} \quad G = \varepsilon, \] (3.3a)

and

\[ \nu(G) = \frac{1}{N} \quad \text{if} \quad G = 1, \]

With regard to this specification we can give an interpretation that in (2.1) we assume the analytical form of \( F \) as \( \frac{\partial F}{\partial G_i} = 0 \). Another interpretation would be that we assume Leontief type\( [5] \) (factor limitation) production function.

\( \psi_i \) stands for an additional cost which is affected by the value of the grade \( G_i \). This is an alternative and easier way of analysing the effect of \( G \) or the production behavior of the ith firm (so to speak G. Becker Version\( [1] \)) compared to the way in which \( G \) is included in the production function of ith firm, as is done in the previous section. By this alternative specification of production function (3.1a) means that the demand curve for labor \( D_i D_i' \) (\( i = \ell, f \)) in Figure 1 are straight lines perpendicular to the abscissas.
where \( N \) stands for the number of the total potential suppliers. By applying (3.3a) to (3.2) we have

\[
\nu_1 = - \frac{(1 - \frac{1}{N})}{(1 - \varepsilon)}
\]  

\[
\nu_0 = \frac{1 + \varepsilon(1 - \frac{1}{N})}{(1 - \varepsilon)}
\]

Hence, the distribution function (3.2) is written as

\[
\nu(G) = 1 + \frac{\varepsilon(1 - \frac{1}{N})}{(1 - \varepsilon)} - \frac{(1 - \frac{1}{N})}{(1 - \varepsilon)} \cdot G
\]

By adopting the magnitude of \( \varepsilon \) as \( \varepsilon = \frac{1}{N} \) (3.2') is written as

\[
\nu(G) = 1 + \frac{1}{N} - G
\]

If \( N \) is sufficiently a large number we have

\[
\nu(G) \equiv 1 - G.
\]

The number of persons with \( G \) higher than \( G_j, N(G \geq G_j) \), is given by

\[
N(G \geq G_j) = N \cdot \nu(G_j)
\]

Hence, applying (3.2'), we obtain

\[
N(G \geq G_j) = N \left[ 1 + \left(1 - \frac{1}{N}\right)\left(\frac{\varepsilon}{1 - \varepsilon}\right) - \left(1 - \frac{1}{N}\right)\left(\frac{\varepsilon}{1 - \varepsilon}\right) \cdot G_j \right]
\]

Making use of the relation \( \varepsilon = 1/N \), (3.7) is written as

\[
N(G \geq G_j) = N + 1 - NG_j = N(1 - G_j) + 1
\]

From (3.2'') we have, as a good approximation for (3.7'),

\[
N(G \geq G_j) \equiv N(1 - G_j)
\]

### 4.1.3. Indirect observation of \( G_i \)

In the simple model, variables \( Q_i^t, L_i^t \) and \( w_i^t \) where \( i \) and \( t \) stands for the production unit and time respectively, are directly observable from the data. However, we cannot observe the magnitude of \( G_i \) directly and we must therefore indirectly measure it making use of the model itself. We shall discuss the procedure to measure \( G_i \) below.
Suppose we have data on \( Q_i^t, L_i^t \) and \( w_i^t \) \((i = \ell, f)\). With respect to the parameters of the model we have \( \nu_0 = 1, \nu_1 = -1 \). Further suppose we have already estimated the parameters, \( \lambda_0 \) and \( \lambda_1 \), in the supply probability function. Labor supply curves for the leader and the follower respectively pass through points \( A_\ell \) and \( A_f \) in Figure 1. The values of the coordinates of these points \( A_\ell \) and \( A_f \) are known from observed data on the wages and employment of the leader and the follower. (Production units (firms, sectors) are ordered by the observed wage rates. Hence, successively, leader-follower relationships can be identified by this ordering.) Therefore, we can obtain \( N^\text{min}_{G_\ell} \) and \( N^\text{min}_{G_f} \) by solving the simultaneous equations,

\[
N^\text{min}_{G_\ell} (\lambda_0 + \lambda_1 w_\ell) = L_\ell
\]

\[
(N^\text{min}_{G_\ell} - N^\text{min}_{G_f})(\lambda_0 + \lambda_1 w_f) = L_f
\]

where actual wages and employment \( w_\ell, w_f, L_\ell \) and \( L_f \) are directly obtained from the observed data and \( \lambda_0 \) and \( \lambda_1 \) are supposed to be already estimated, as mentioned above.

Applying \( N^\text{min}_{G_\ell} \) and \( N^\text{min}_{G_f} \) thus obtained to the left hand side of the grade distribution function \( \nu(G_i) = 1 - G_i \) in [3.2], we can calculate the numerical values for \( G^\text{min}_\ell \) and \( G^\text{min}_f \). These are the “indirectly observed” values for \( G^\text{min}_\ell \) and \( G^\text{min}_f \).

### 4.1.4. Equation of Supply-probability

We specify the supply-probability equation (2.2) as a linear function of \( w \)

\[
\mu = \lambda_0 + \lambda_1 w
\]

where as shown later

\[
\lambda_0 < 0, \quad \lambda_1 > 0 \quad \text{and} \quad 0 \leq \mu \leq 1
\]

are postulated. \( ^6 \) In order to make our model simple without impairing its basic characteristics, we use a linear function as a supply probability function. This simplification means that we implicitly employ a rectangular distribution for the minimum supply price of labor, \( w \). In equation (3.8), we have \( w = \lambda_0 / \lambda_1 \) when \( \mu = 0 \). hence,

\[
\mu = 0 \quad \text{if} \quad w \leq -\frac{\lambda_0}{\lambda_1}
\]

\[
\mu = 1 \quad \text{if} \quad w \geq -\frac{1 - \lambda_0}{\lambda_1}
\]

and for the range of \( w \),

\[
-\frac{\lambda_0}{\lambda_1} < w < \frac{1 - \lambda_0}{\lambda},
\]
Figure 3

(3.8) holds. The supply probability curve with the characteristics (3.8) and (3.10) is depicted in Figure 3.

The numerical value of $-\lambda_0/\lambda_1$, stands for the minimal value of the range of distributed values of $w$. This minimal values of $w$ must be positive, and

$$-\frac{\lambda_0}{\lambda_1} > 0 \quad (3.11)$$

must hold. On account of the nature of the distribution function, $\lambda_1$ must be positive. Hence, from (3.11) we have

$$\lambda_0 < 0 \quad (3.12)$$

4.2. Behavior of the Leader in the alternative Simple Model

4.2.1. Basic Equations

Let the leader’s production function be (3.1a), and we have

$$Q_\ell = b_\ell L_\ell \quad (L.1)$$

where the suffix $i$ in (3.1a) is replaced by $\ell$ to show that the equation is that of the leader.

The cost function in (4.1.1) can be written as

$$C_\ell = \psi_\ell(G_{\ell}, L_\ell) + w_\ell L_\ell \quad (L.2)$$

where 7

7If the true shape of $\mu$ function is linear as shown in (3.8) $\lambda_0 < 0$ must be held in the estimated relation as well. However, if the true function is non-linear, linear supply probability function, $\lambda_0 + \lambda_1 w$, originally is an approximation. Hence, a constant term in an estimated linear supply probability function could be negative.

7Here after, for the sake of brevity, we assume $G_{\ell} \approx G_{\ell}$ where $G_{\ell}$ stands for $G_{\ell}^{\text{min}}$. By this approximation the basic characteristics of the model will not be impaired.
The number of suppliers to the leader is given by (letting \( N \) be population of working age)

\[
L^*_\ell = \mathbb{N}[\nu(G_{\ell}) - \nu(G_{\ell}^{max})] \cdot \mu(w_{\ell})
\]

or

\[
L^*_\ell = \mathbb{N}[\nu(G_{\ell}) - \nu(G_{\ell}^{max})] \cdot (\lambda_0 + \lambda_1 w_{\ell} + \lambda_2 A)
\]

where \( A \) stands for the effect of changing \( \pi_2 \) in sec. 2.3. (L.3) corresponds to (2.6). This equation states that effective suppliers to the leader must be the ones with at least grade \( G_{\ell} \).

When the value of \( Q_{\ell} \) is given (L.3) can be written as (taking into account (L.1),)

\[
\frac{1}{b_{\ell}} Q_{\ell} = \mathbb{N}[\nu(G_{\ell}) - \nu(G_{\ell}^{max})] \cdot \mu(w_{\ell})
\]

We minimize \( C_{\ell} \) in (L.2) under the constraint (L.3'). That is, defining \( F \) as

\[
F = \psi_{\ell}(G_{\ell}, L_{\ell}) + w_{\ell} L_{\ell} + \lambda \left[ \frac{1}{b_{\ell}} Q_{\ell} - \mathbb{N}[\nu(G_{\ell}) - \nu(G_{\ell}^{max})] \cdot \mu(w_{\ell}) \right]
\]

where \( \lambda \) is a Lagrangian multiplier,

\[
\frac{\partial F}{\partial G_{\ell}} = \frac{\partial F}{\partial w_{\ell}} = 0
\]

has to hold if \( C_{\ell} \) is minimized. Hence, from \( \frac{\partial F}{\partial G_{\ell}} = 0 \), we have

\[
\frac{\partial \psi_{\ell}}{\partial G_{\ell}} + \lambda \left[ -\mathbb{N} \frac{d\nu(G_{\ell})}{dG_{\ell}} \cdot \mu(w_{\ell}) \right] = 0
\]

From \( \frac{\partial F}{\partial w_{\ell}} \), we have

\[
L_{\ell} - \lambda \mathbb{N}[\nu(G_{\ell}) - \nu(G_{\ell}^{max})] \cdot \frac{d\mu}{dw_{\ell}} = 0
\]

Taking into account (3.8) we have \( \frac{d\mu}{dw_{\ell}} = \lambda_1 \). Hence, from (L.6) and (L.7) we get the minimization condition

\[
\frac{-\frac{\partial \psi_{\ell}}{\partial G_{\ell}}}{\mu(w_{\ell})} = \frac{1}{b_{\ell}} Q_{\ell} \frac{(G_{\ell}^{max} - G_{\ell})}{\lambda_1}
\]
where $G_{\ell}^{max}$ is given. We can solve (L.8) and (L.3') simultaneously for $G_\ell$ and $w_\ell$. From (L.8) and (L.3')

$$-\frac{\partial \psi_\ell}{\partial G_\ell} = \frac{N}{\lambda_1} [\mu(w_\ell)]^2$$  \hspace{1cm} (L.9)

To begin with the simplest case we assume $\frac{\partial \psi_\ell}{\partial G_\ell}$ to be a linear function, that is,

$$\frac{\partial \psi_\ell}{\partial G_\ell} = \delta_0 + \delta_2 L_\ell$$  \hspace{1cm} (L.10)

where $\delta_0$, $\delta_1$ and $\delta_2$ are the parameters, and,

$$\frac{\partial \psi_\ell}{\partial G_\ell} < 0$$  \hspace{1cm} (L.11)

must hold.

Inserting (L.10) into (L.9) and making use of (L.3), we have

$$\delta_0 + \delta_2 L_\ell = \frac{-\left[\frac{1}{\lambda_1} Q_\ell \right]^2}{N(G_{\ell}^{max} - G_\ell)^2 \lambda_1}$$  \hspace{1cm} (L.12)

From this we have

$$G_\ell = G_{\ell}^{max} \pm \sqrt{-\left[\frac{1}{\lambda_1} Q_\ell \right]^2 \frac{1}{N\lambda_1 (\delta_0 + \delta_2 L_\ell)}}$$  \hspace{1cm} (L.13)

Taking into account $G_\ell < G_{\ell}^{max}$ we adopt

$$G_\ell = G_{\ell}^{max} - \sqrt{-\left[\frac{1}{\lambda_1} Q_\ell \right]^2 \frac{1}{N\lambda_1 (\delta_0 + \delta_2 L_\ell)}}$$  \hspace{1cm} (L.13')

where

$$\delta_0 + \delta_2 L_\ell < 0.$$

(L.13') is the “leader solution” of the grade variable.

Taking into account $\nu(G_\ell) - \nu(G_{\ell}^{max}) = G_{\ell}^{max} - G_\ell$, (L.3) can be written as,

$$L_\ell = \overline{N}(G_{\ell}^{max} - G_\ell)(\lambda_0 + \lambda_1 w_\ell + \lambda_2 A)$$  \hspace{1cm} (L.3')

where $A$ stands for the effect of changing $\pi_g$ in sec. 2.3.

From (L.3')
Substituting $G_f$ in (L.14) by (L.13') we obtain

$$w_f = \frac{1}{\lambda_1} \cdot \frac{L_f}{N} \cdot \sqrt{- \frac{1}{\lambda_1} \cdot \left( \frac{1}{b_f} Q_f \right)^2} - \frac{\lambda_0}{\lambda_1} \cdot \frac{\lambda_2}{\lambda_1} A$$

or

$$w_f = \frac{1}{\lambda_1} \cdot \frac{1}{b_f} \cdot \frac{Q_f}{N} \cdot \sqrt{- \frac{1}{\lambda_1} \cdot \left( \frac{1}{b_f} Q_f \right)^2} - \frac{\lambda_0}{\lambda_1} \cdot \frac{\lambda_2}{\lambda_1} A$$

This is the “leader solution” of the wage variable.

4.3. Behavior of the Follower in the Simple Model

Let the production function and the cost function of the follower be respectively,

$${Q_f} = b_f L_f$$  \hspace{1cm} (F.1)

and

$${C_f} = \psi_f(G_f, L_f) + w_f L_f$$  \hspace{1cm} (F.2)

where $G_f$ stands for the minimum value of the grade indicator of labor the follower can accept. $G_f^{max}$ is the maximum value of the grade indicator which the follower can attain. When $Q_f$ is given (F.3) can be written as

$$L_f^* = \frac{1}{N} \left[ \nu(G_f) - \nu(G_f^{max}) \right] \cdot \mu(w_f)$$  \hspace{1cm} (F.3)
\[
\frac{1}{b_f} Q_f = N [\nu(G_f) - \nu(G_f^{\text{max}})] \cdot \mu(w_f) \quad (F.3')
\]

We minimize \( C_f \) in \( (F.2) \) with constraint \( (F.3') \). The values of \( w_f \) and \( G_f \) minimizing \( C_f \) can be given by,

\[
\frac{\partial F}{\partial G_f} = \frac{\partial F}{\partial w_f} = 0, \quad (F.4)
\]

where

\[
F = \psi_f(G_f, L_f) + w_f L_f + \Lambda \left[ \frac{1}{b_f} Q_f - N [\nu(G_f) - \nu(G_f^{\text{max}})] \cdot \mu(w_f) \right] \quad (F.5)
\]

From \( (F.4) \) we get

\[
\frac{\partial \psi_f}{\partial G_f} \frac{1}{\mu(w_f)} = \frac{1}{b_f} Q_f \quad (F.6)
\]

Making use of \( (F.6) \) and \( (F.3') \) we have

\[
- \frac{\partial \psi_f}{\partial G_f} = \frac{N}{\lambda_1} \cdot [\mu(w_f)]^2 \quad (F.7)
\]

We assume \( \frac{\partial \psi_f}{\partial G_f} \) to be linear, that is

\[
\frac{\partial \psi_f}{\partial G_f} = \varepsilon_0 + \varepsilon_2 L_f \quad (F.8)
\]

Using \( (F.3) \)

\[
\mu(w_f) = \frac{L_f}{N [\nu(G_f) - \nu(G_f^{\text{max}})]} \quad (F.9)
\]

where

\[
\nu(G_f) = 1 - G_f \quad (F.10)
\]

and

\[
\nu(G_f^{\text{max}}) = 1 - G_f \quad (F.11)
\]

because \( G_f^{\text{max}} = G_f \).

Hence
(\nu(G_f) - \nu(G_f^{max})) = (1 - G_f) - (1 - G_\ell) = G_\ell - G_f \quad (F.12)

Taking into account (F.8), (F.9) and (F.12), (F.7) is rewritten as

\[ \varepsilon_0 + \varepsilon_2 L_f = -\frac{N}{\lambda_1} \left[ \frac{L_f^2}{N^2(G_\ell - G_f)^2} \right] \quad (F.13) \]

where \( G_\ell \) is given by the solution for the leader. Again we suppose \( \varepsilon_1 = 0 \) for brevity. Hence (F.14) can be written as

\[ \varepsilon_0 + \varepsilon_2 L_f = \frac{-\left(\frac{1}{b_f}Q_f\right)^2}{N(G_\ell - G_f)^2\lambda_1} \quad (F.14) \]

From this we have

\[ G_f = G_\ell \pm \sqrt{\frac{-\left(\frac{1}{b_f}Q_f\right)^2}{N\lambda_1(\varepsilon_0 + \varepsilon_2 \frac{1}{b_f}Q_f)}} \quad (F.15) \]

Because \( G_f < G_\ell \) we adopt

\[ G_f = G_\ell - \sqrt{\frac{-\left(\frac{1}{b_f}Q_f\right)^2}{N\lambda_1(\varepsilon_0 + \varepsilon_2 \frac{1}{b_f}Q_f)}} \quad (F.16) \]

where

\[ \varepsilon_0 + \varepsilon_2 L_f < 0. \]

(F.16) corresponds to \((L.13')\) in the leader’s case, and gives the “follower’s solution” of the grade variable. From (F.3) and (F.12), we have

\[ L_f = \overline{N}(G_f^{max} - G_f)(\lambda_0 + \lambda_1w_f + \lambda_2A) \quad (F.17) \]

By solving (F.17) we get

\[ w_f = \frac{L_f}{\lambda_1\overline{N}(G_f^{max} - G_f)} - \frac{\lambda_0}{\lambda_1} - \frac{\lambda_2}{\lambda_1}A \quad (F.18) \]

Substitution of \( G_f \) in (F.18) by (F.15) gives
An Equilibrium Model of Continually Heterogeneous Labor Market

\[ w_f = \frac{1}{\lambda_1} \cdot \frac{L_f}{N} - \frac{\lambda_0}{\lambda_1} - \frac{\lambda_2}{\lambda_1} A \]  \hspace{1cm} (F.19)

or

\[ w_f = \frac{1}{\lambda_1} \cdot \frac{Q_f}{b_f} - \frac{\lambda_0}{\lambda_1} - \frac{\lambda_2}{\lambda_1} A \]  \hspace{1cm} (F.19')

This is the “follower solution” of the wage variable.

5. Application of the alternative Simple Model to Japanese data

The result of application of the model in the previous section to Japanese data is shown in this section.

It can be seen the wage of financial sector is always at the top of the wage differential among the sectors (industries) during the observational period, 1970 through 1991. Hence financial sector can be identified as “leader sector”. The other sectors are aggregated and can be identified as “follower sector” as is shown by Figure 4. Hence, application of the model of leader behavior and follower behavior is straightforward.

The observed yearly values of \( w_i, L_i \) and \( Q_i(i = \ell, f) \) were obtained from SNA data arranged by Economic Planning Agency. Observational period is 1970 through 1991. These are shown in Table 3.

The estimated values of the parameters \( \lambda_0, \lambda_1 \) are shown in Table 2.

Indirectly observed values obtained by using the estimation method in 4.1.3 function are shown in Table 3. Estimated values of \( \delta_0 \) and \( \delta_1 \) are also shown in Table 2. The estimated and observed values for \( w_i, G_i \) (i = \( \ell, f \)) are shown in Table 3. The estimated and observed values for \( w_i \) and \( G_i \) (i = \( \ell, f \)) are shown in Figure 4 and Figure 5.

9 In case where the order of wage differential (i.e., top, second, third etc.) change during observational period, the application of the models of leader and follower was discussed in (3.4).

10 In this section \( \mu \) is specified as \( \mu = \lambda_0' + \lambda_1 w + \lambda_2 A \) where \( A \) affects the changes in \( \pi_0 \) in (2.3). However, values of \( A \) to be observed were substituted by time trend, that is, \( \mu = \lambda_0' + \lambda_1 w + \alpha t \) where \( \alpha \) stands for the coefficient of the time trend term. \( \lambda_0' \) could be negative as shown in footnote 6.
6. Conclusion

From these results obtained in Figure 4, we can conclude that the “alternative simple model of the continually heterogeneous labor market” seems to be applicable to the Japanese data.

This model would also be applicable to the growth mechanism of developing economies as was shown elsewhere[8].
